Use of Satellite Observations to Measure Air-Sea Coupling and to Validate Its Estimates from Numerical Atmospheric Models

Natalie Perlin, Dudley Chelton, Simon de Szoeke

College of Earth, Ocean, and Atmospheric Sciences, Oregon State University

24 July 2013

NOAA/NESDIS Cooperative Research Program 9th Annual Symposium
UW Pyle Center, Madison, WI
Outline

• Satellite products of mesoscale ocean winds and sea surface temperatures
• Air-sea coupling evidence from satellite products
• Atmospheric modeling simulations in Agulhas Return Current region
• Different PBL parameterizations -> different solutions
• Validating of modeled air-sea coupling using satellite estimates
• Role of vertical turbulent mixing in successful surface wind prediction
Satellite products to study air-sea coupling

• SeaWinds scatterometer onboard QuikSCAT satellite (1999-2009): Multi-year measurements of ocean winds, nearly global daily coverage on a 0.25° grid, product of NASA/Jet Propulsion Laboratory

• NOAA Sea Surface Temperatures, Optimum Interpolation based on AMSR-E and AVHRR satellite products, daily on a 0.25° grid (2002-2011)
Air-sea interaction: scale dependency

Larger scales > 1000km: Negative correlations are found between the sea surface temperature (SST) and wind speed (Xie, 2004)

=> Atmosphere is driving the ocean (one-way forcing)

Ocean mesoscales <1000 km: Positive correlation has been found between the mesoscale SST variations and near-surface wind speed and surface fluxes (Chelton et al., 2001; O’Neill et al., 2005)

=> Ocean is forcing the atmosphere (possible two-way interaction)

Coupling of SST and wind stress magnitude

High-pass filtered wind stresses (colors) and SST (contours)

(From Small et al., 2008) Fig. 2. Maps of spatially high-pass filtered 2 months (May–June 2003) average wind stress magnitude (Nm$^{-2}$, color) and SST (°C, contours, interval 0.5 °C, zero contour omitted). Data from QuikSCAT scatterometer and AMSR-E. (a) North-west Pacific, Kuroshio region, (b) North-west Atlantic, Gulf Stream and North Atlantic Current region, (c) South-west Atlantic, Brazil-Malvinas confluence, and (d) Southern Indian Ocean, Agulhas Return Current.
Atmospheric model simulations: WRF and COAMPS

Weather Research and Forecast model - NCAR/NOAA/NCEP

COAMPS model (atmospheric component) - Naval Research Laboratory

Monthly average of satellite SST estimate (°C) for July 2002, from NOAA OI 0.25° daily SST analysis. Black rectangles outline the location of model simulations domains, outer and nested domains having 75km and 25km grid box spacing, respectively. There are 50 vertical levels in each of the model grids, stretching from the ground to about 18km; 22 levels lie in the lowest 1000m.
## Atmospheric model simulations: WRF and COAMPS

The models are initialized and forced with global NCEP FNL Operational Global Analysis data on 1.0°x1.0° grid at 6-h intervals, the product from the Global Data Assimilation System (GDAS) and NCEP Global Forecast System (GFS) model.

(*) – GBM: Grenier-Bretherton-McCaa PBL scheme, implemented in WRFv3.3 (local), WRFv3.5 (public)
PBL parameterization and turbulent vertical mixing schemes

The momentum equation for the u-component of horizontal flow:

\[
\frac{\partial u}{\partial t} = -u \frac{\partial u}{\partial x} - v \frac{\partial u}{\partial y} - w \frac{\partial u}{\partial z} - \frac{1}{\rho} \frac{\partial P}{\partial x} + vf - \frac{\partial (u' w')}{\partial z}
\]

Subgrid scale vertical turbulent flux to be parameterized!!!!

1.5-order turbulent closure schemes: all level ~2.5 by Mellor and Yamada (1974, 1982) classification

\[
K_M = l \cdot q \cdot S_M
\]

\[
q = \sqrt{(u'^2 + v'^2 + w'^2)}
\]

Second-order moment!!!

Subgrid scale vertical turbulent flux to be parameterized!!!!

flux \propto to local gradient

\[
u' w' = -K_M \frac{\partial u}{\partial z} \rightarrow - \frac{\partial (u' w')}{\partial z} = \frac{\partial}{\partial z} \left( K_M \frac{\partial u}{\partial z} \right),
\]

Eddy/turbulent mixing coefficient

\[
\frac{\partial (u' w')}{\partial z} = \frac{\partial}{\partial z} \left( K_M \frac{\partial u}{\partial z} - \gamma_c \right),
\]

counter-gradient term

Non-local-K schemes: often based on Troen and Mahrt (1986)

\[
K_M = k w_s z \left( 1 - \frac{z}{h} \right)^p
\]

boundary layer height

Second-order moment!!!
SST from NOAA IO 0.25° satellite-base data product: daily for July 2002
Surface winds and sea level pressure: July 2002
Monthly-average near-surface wind response

July 2002 average of 10-m ENS wind perturbations (color), and satellite NOAA AMSR-E/ Reynolds OI SST perturbations (contours, interval 1°C, zero contour omitted, negative dashed). Perturbations result from high-pass filtering, which removes the larger-scale signal; filtering involved loess smoother with 30° longitude and 10° latitude. Wind perturbations are computed for (top left) QuikSCAT satellite wind product (version 4), smoothed with 1.25° x 1.25° loess filter; (other panels) models (WRF v3.3 or COAMPS v4) as indicated, with various turbulent mixing schemes.
Air-sea coupling metric: coupling coefficients

Coupling coefficients between ENS 10-m wind perturbations and SST perturbations fields. Coupling coefficients are estimated as a linear regression slope (red line, marked $s$ values in each panel) of bin-averaged quantities (black dots); shaded gray areas show plus/minus standard deviation for each bin. Dashed blue lines indicate bin population (right blue y-axis). Estimates include range of SST perturbations of approximately from -3°C to +3°C (bins containing >50 data points).
Coupling of SST- and wind stress derivatives

(From Hashizume et al., 2002; courtesy of D. Chelton, CEOAS/OSU)

Schematic illustration of the divergence and curl of the wind and wind stress fields that result from spatial variations of the SST field. Near a meandering SST front (the heavy black line), surface winds are lower over cool water and higher over warm water, shown qualitatively by the lengths of the vectors. Acceleration where winds blow across the SST front generates divergence (green area). Lateral variations where winds blow parallel to the SST front generate curl (red area). The divergence and curl perturbations are proportional to the downwind and crosswind components of the SST gradient, respectively.
Coupling of SST- and wind/wind stress derivatives from QuikSCAT

- Wind stress curl – crosswind SST gradient
- ENS wind – crosswind SST gradient
- Wind stress divergence – downwind SST gradient
- ENS wind divergence – downwind SST gradient

Eddy mixing coefficients and coupling coefficients

Average $K_m$ on 0.25° grid, nested domain

Height-average $K_m$ (0-4km) vs. coupling coefficient

Correlation coefficient: 0.75
Conclusions

• Coupling coefficient for QuikSCAT ENS winds and NOAA OI SST in Agulhas Return Current Region for July 2002 results in 0.42 m s\(^{-1}\) °C\(^{-1}\), and is consistent with earlier estimates for that area

• Turbulent mixing / PBL parameterizations in atmospheric models play an important role in successful prediction of surface wind response to mesoscale SST changes

• WRF simulations with the newly implemented Grenier-Bretherton-McCaa PBL scheme agrees best with QuikSCAT estimates of coupling coefficients, yielding 0.40 m s\(^{-1}\) °C\(^{-1}\)

• The strength of ENS wind coupling coefficient is found to correlate with the height-average eddy mixing coefficient (eddy viscosity) estimated by the PBL scheme

• Model experiments that agree better with QuikSCAT satellite observations of surface winds are likely more reliable to study vertical structure of winds
Acknowledgements

This research has been supported by the NASA Grant NNX10AE91G.

We thank Richard W. Reynolds (NOAA) for guidance to obtain SST data used for WRF simulations, Larry O’Neill (CEOAS/COAS) for providing QuikSCAT satellite data for the study region, and Roger M. Samelson (CEOAS/COAS) for guidance in analyzing turbulence mixing parameterizations.
