

# Evaluation of a first IASI-NG channel selection for Numerical Weather Prediction

**Francesca Vittorioso, Vincent Guidard, Nadia Fourrié**

CNRM, Météo-France & CNRS, GMAP/OBS  
*francesca.vittorioso@meteo.fr*

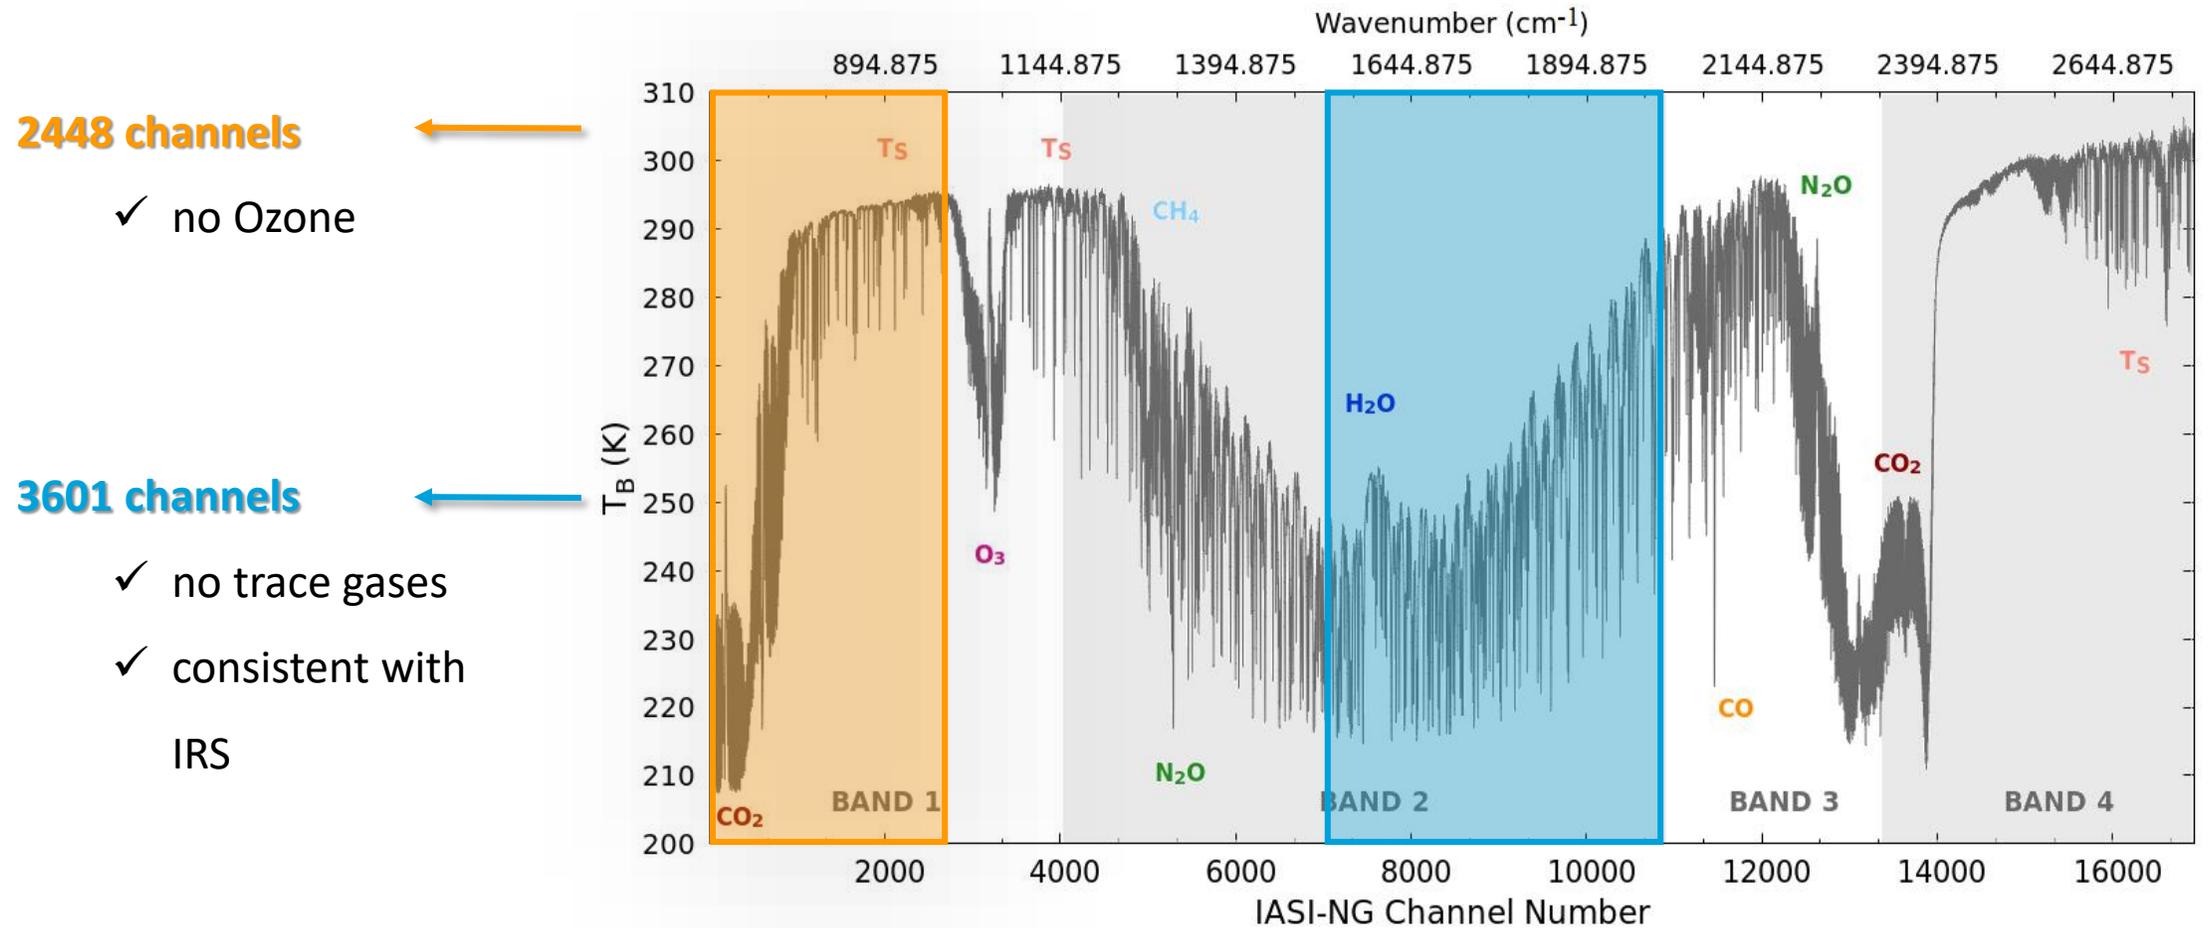

# Objectives

## Why a channel selection

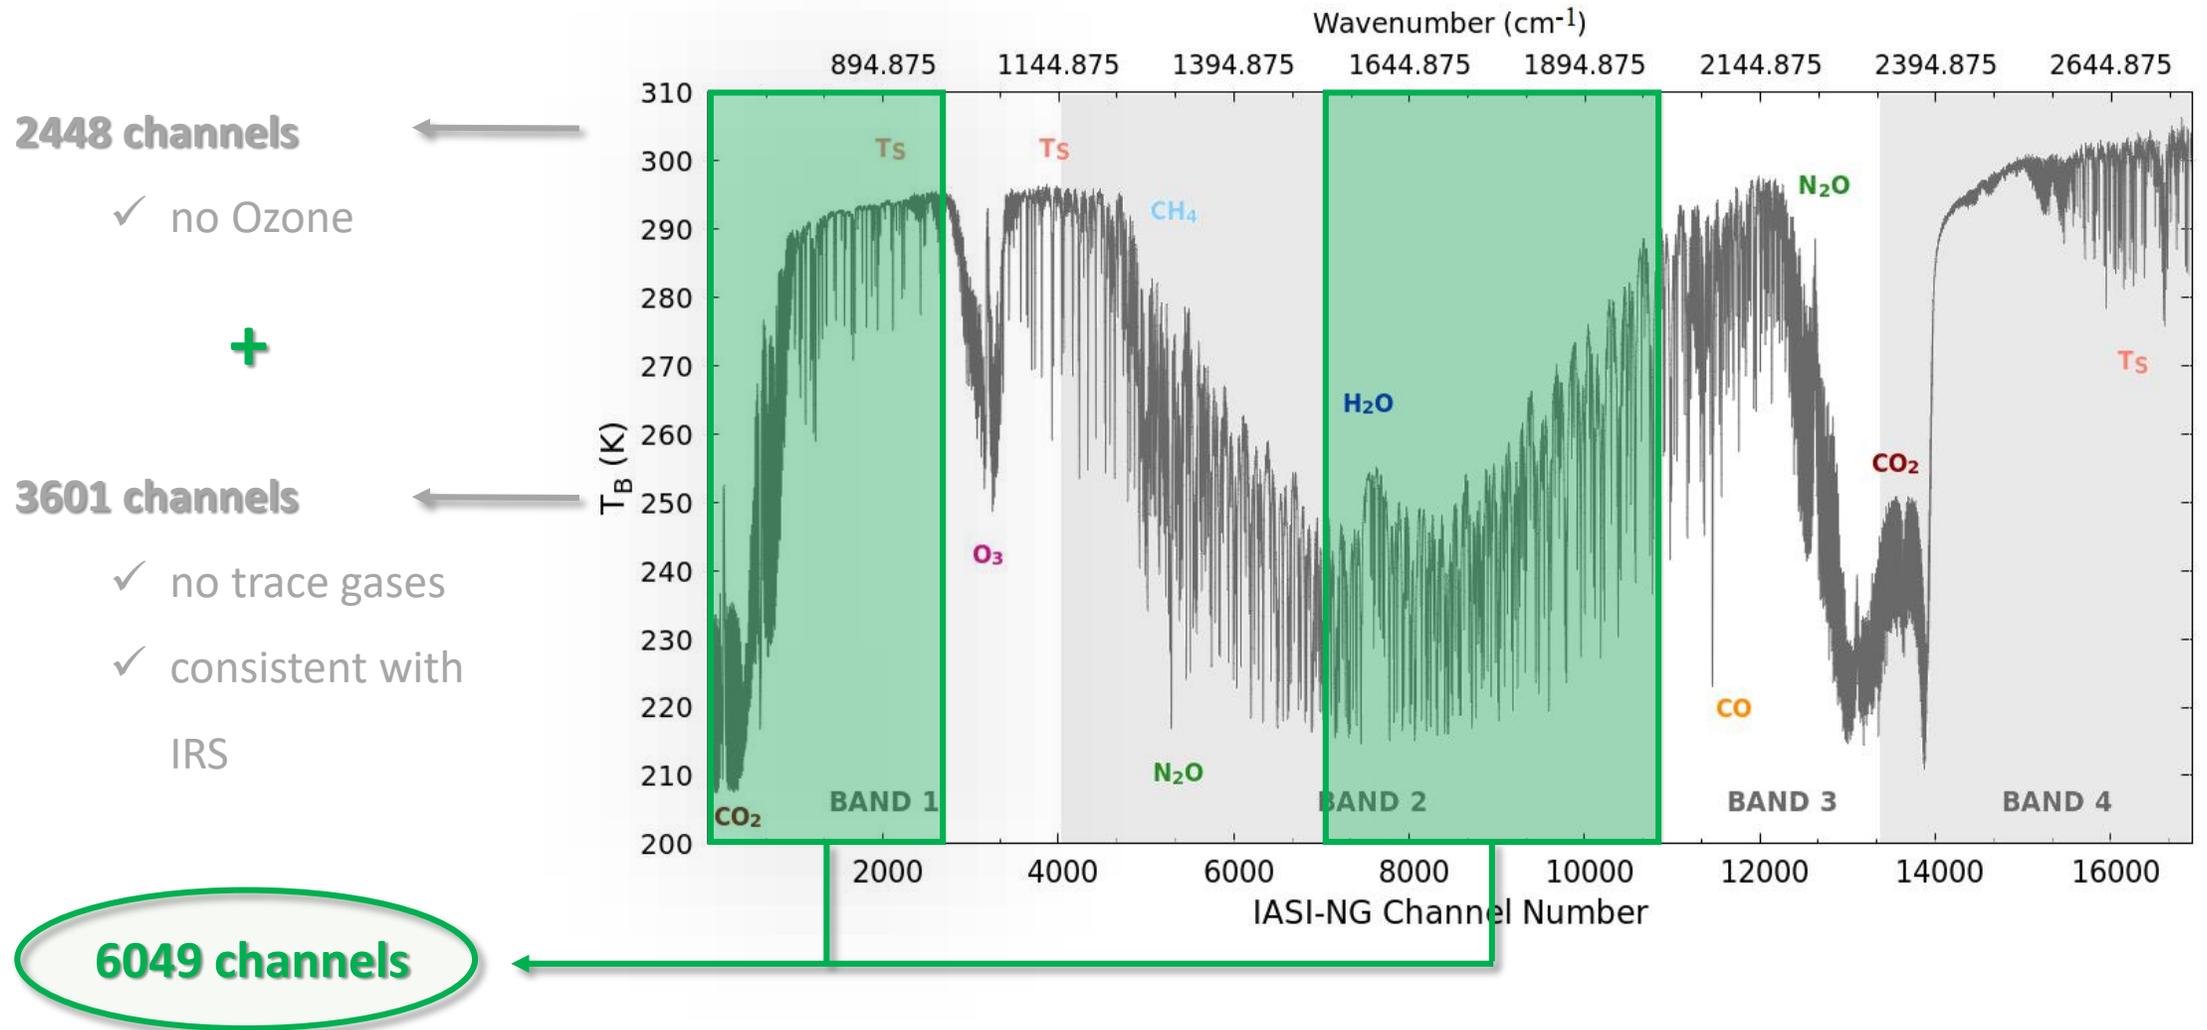

- High amount of data resulting from IASI-NG
  - Many challenges in the areas of data storage and assimilation
  - The number of individual pieces of information will be not exploitable in an operational Numerical Weather Predictions (NWP) context
- ➔ **An appropriate IASI-NG channel selection is needed, aiming to select the most informative channels for NWP models**

# Context

# Context

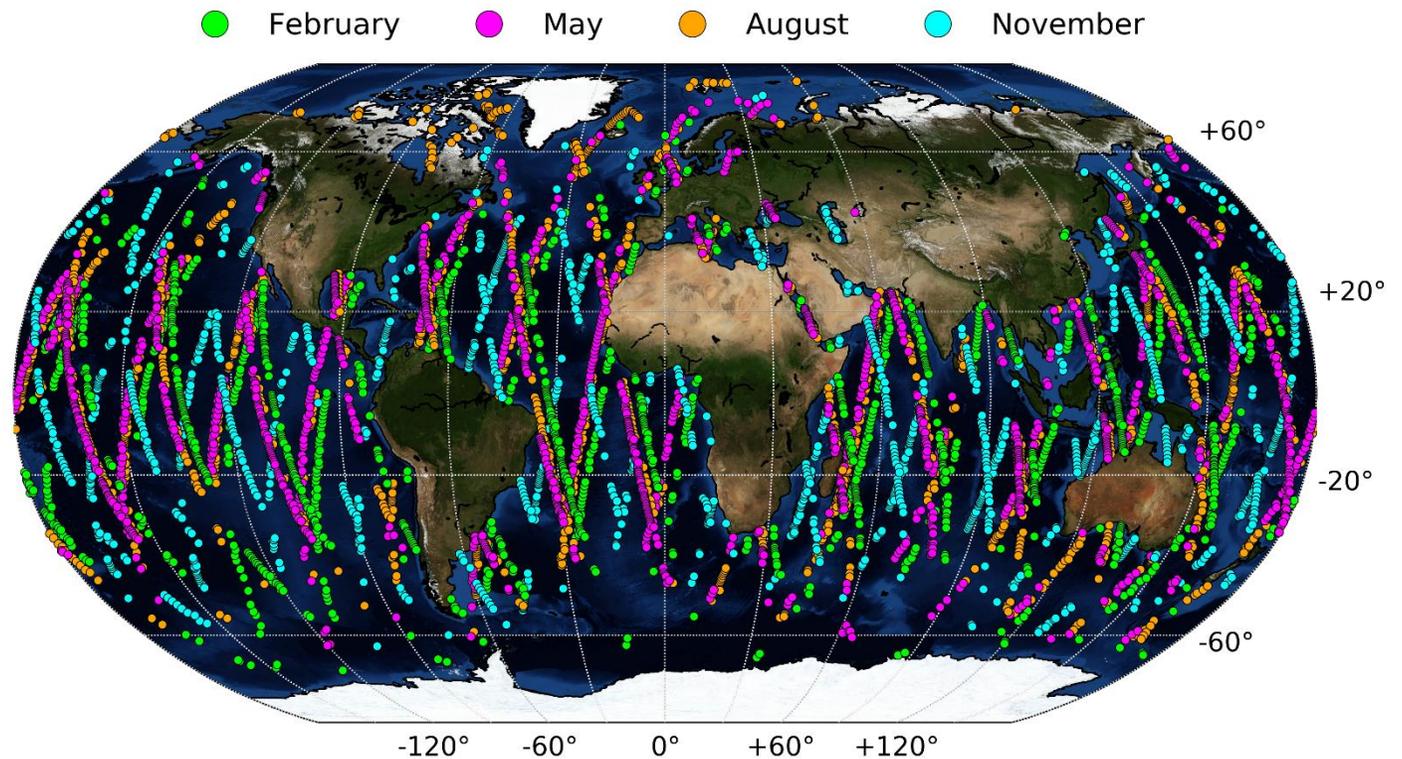

# Case Study

Full IASI orbit computed, for a total amount of 5242448 simulations for each instrument (IASI scan geometry used for IASI-NG) [[Andrey-Andrés et al. \(2018\)](#)]

- ✓ **Nadir**
- ✓ **Over sea**
- ✓ **Clear sky**
- ✓ **Day/night illumination conditions**

30210 observations matching these criteria

**6267 profiles** judged to be a **representative sample**

# Preparatory study towards the channel selection

## 1D-Var retrievals

$$J(\mathbf{x}) = \underbrace{\frac{1}{2} (\mathbf{x} - \mathbf{x}_b)^T \mathbf{B}^{-1} (\mathbf{x} - \mathbf{x}_b)}_{\text{Background}} + \underbrace{\frac{1}{2} [\mathbf{y} - H(\mathbf{x})]^T \mathbf{R}^{-1} [\mathbf{y} - H(\mathbf{x})]}_{\text{Observations}}$$

$\mathbf{x}$  = model state vector  
(Temperature, Humidity, Skin Temperature)  
 $\mathbf{x}_b$  = background state vector  
 $\mathbf{y}$  = vector of observations

$\mathbf{B}$  = background-error covariance matrix  
(provided in NWPSAF 1D-Var package)  
 $\mathbf{R}$  = observation-error covariance matrix  
 $H$  = observation operator

# Preparatory study towards the channel selection

$$J(\mathbf{x}) = \frac{1}{2} (\mathbf{x} - \mathbf{x}_b)^T \mathbf{B}^{-1} (\mathbf{x} - \mathbf{x}_b) + \frac{1}{2} [\mathbf{y} - H(\mathbf{x})]^T \mathbf{R}^{-1} [\mathbf{y} - H(\mathbf{x})]$$

## Observation error estimation

The previous generation of channel selection schemes ignored, or represented just roughly, spectrally correlated errors [e.g. [Rabier et al. \(2002\)](#), [Collard \(2007\)](#)]. This often limited the accuracy of the assimilation process.

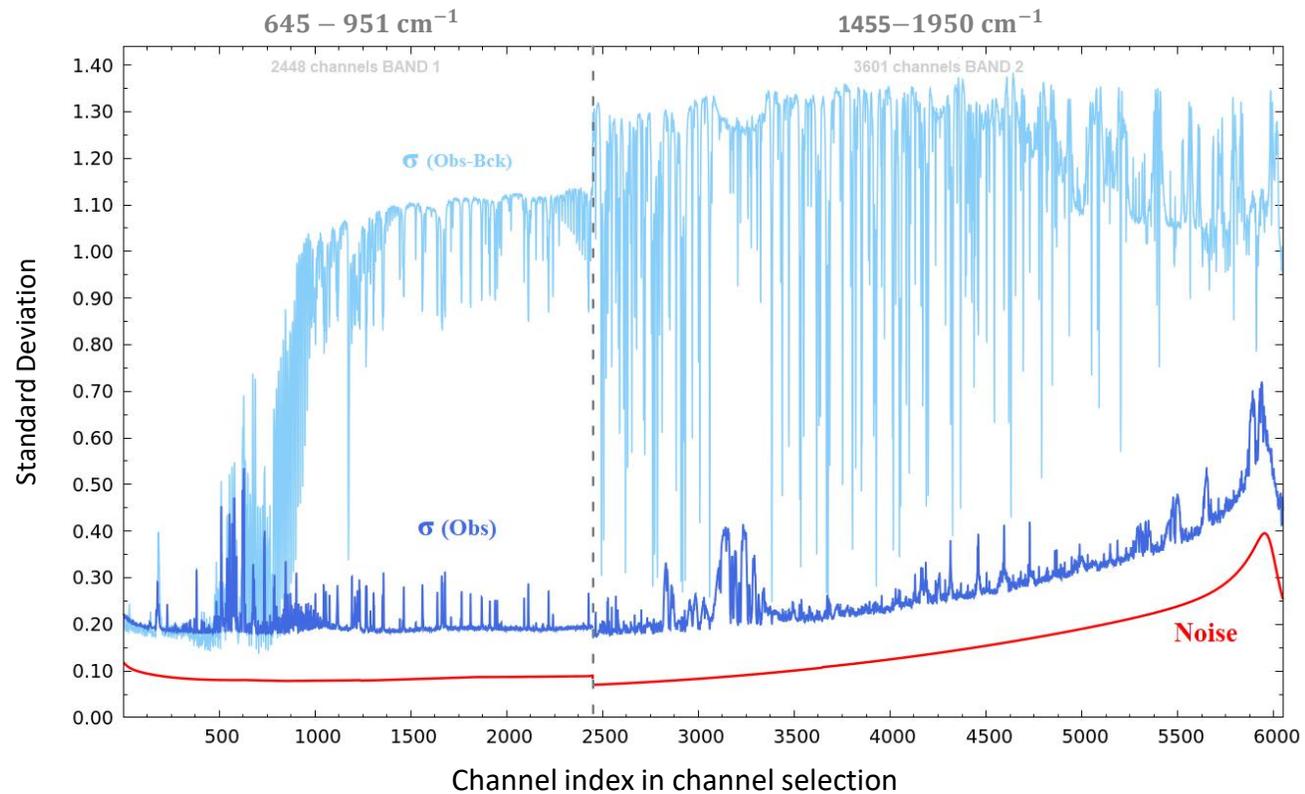

To estimate full  $\mathbf{R}$  matrices, a diagnostic procedure introduced by [Desroziers et al. \(2005\)](#) was implemented.

$$\mathbf{R} = E\left\{ \underbrace{[\mathbf{y} - H(\mathbf{x}_a)]}_{(Observ - Analysis)} \underbrace{[\mathbf{y} - H(\mathbf{x}_b)]^T}_{(Observ - Backg)} \right\}$$

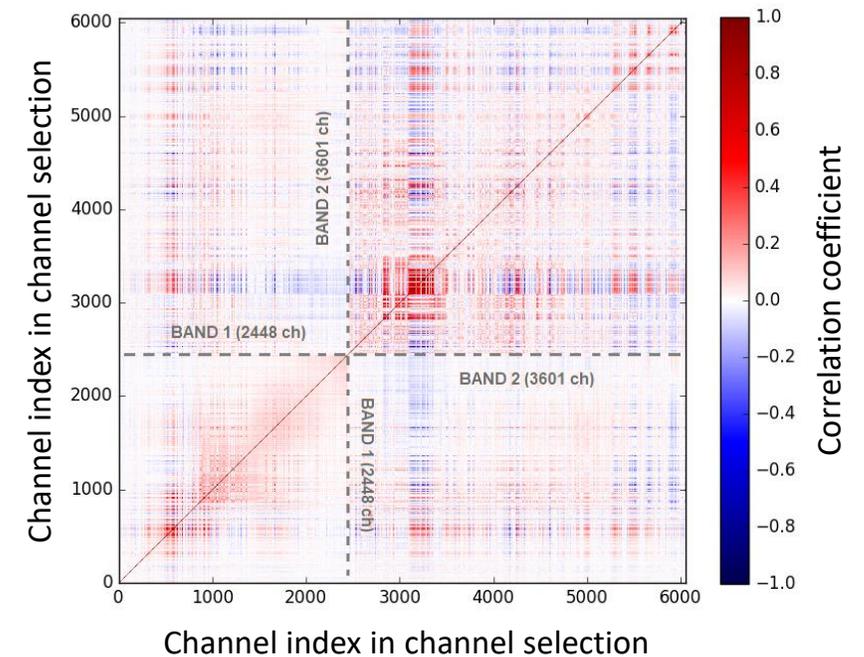

*(Observ - Analysis) (Observ - Backg)*

# Preparatory study towards the channel selection

Diagnostic error standard deviations from 1D-Var output and instrument noise  
6049 channels

Diagnostic for correlation matrix  
6049 channels from BAND 1 and BAND 2

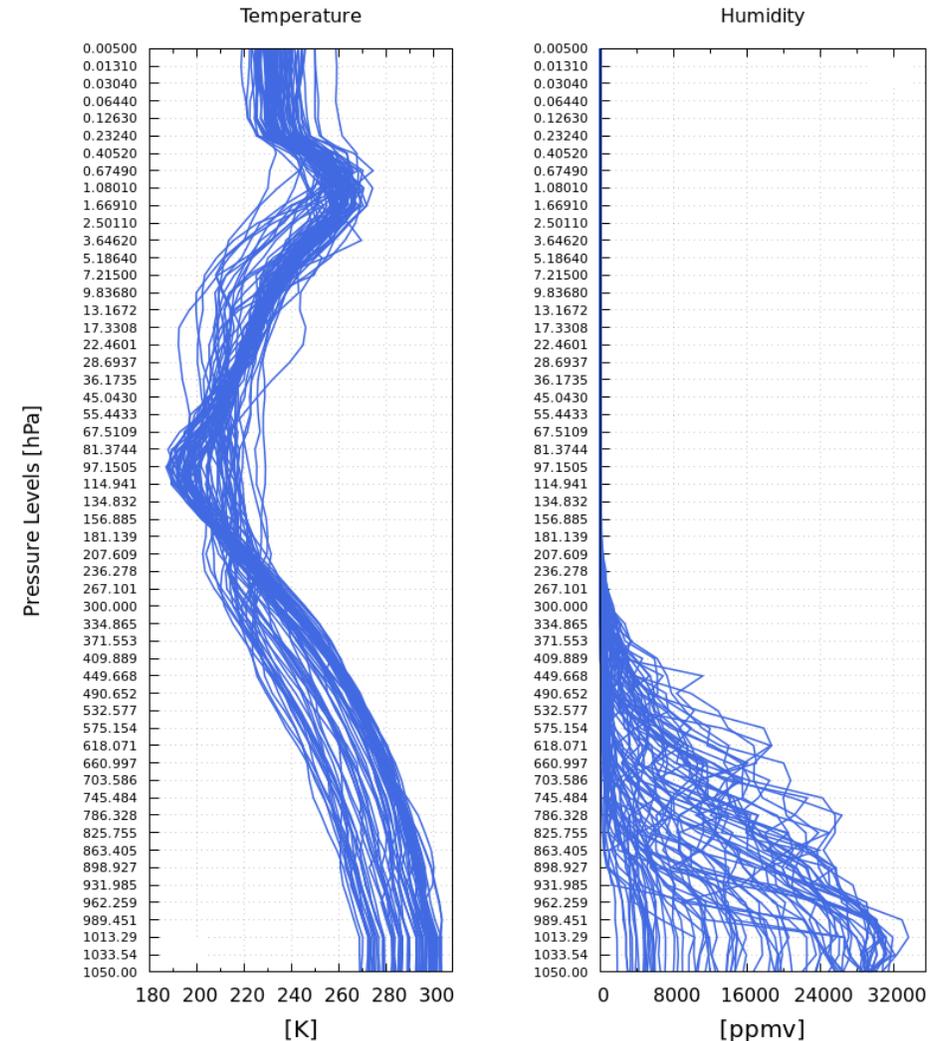

# Case Study for Channel Selection

6267 profiles case study set can be further thinned

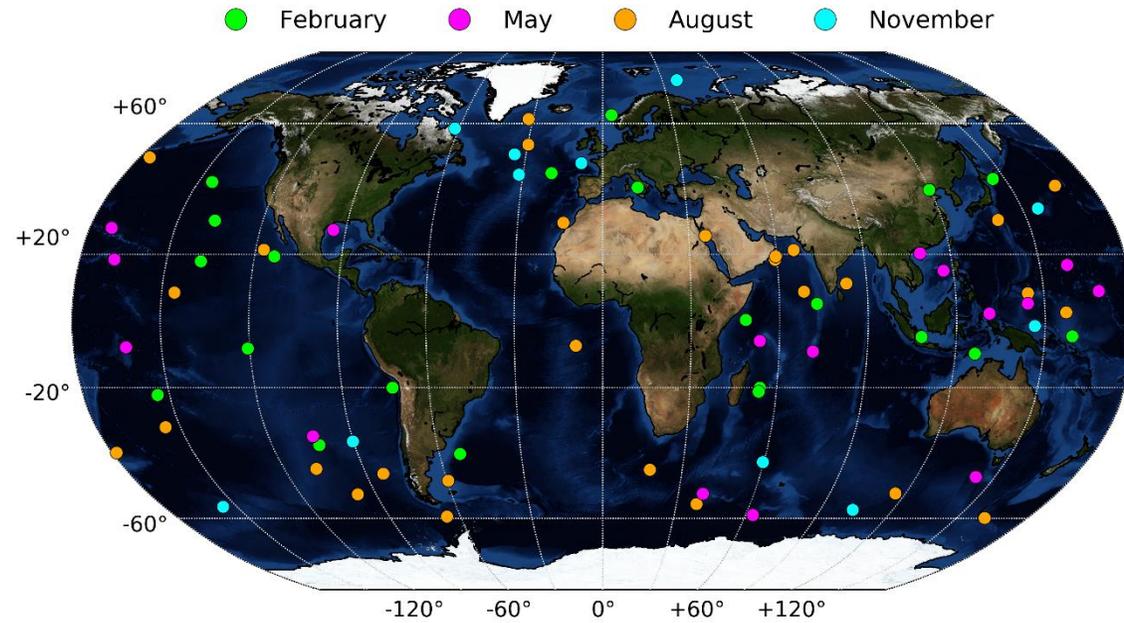

Agglomerative hierarchical clustering technique:

profiles grouped by evaluating distance in terms of temperature and humidity

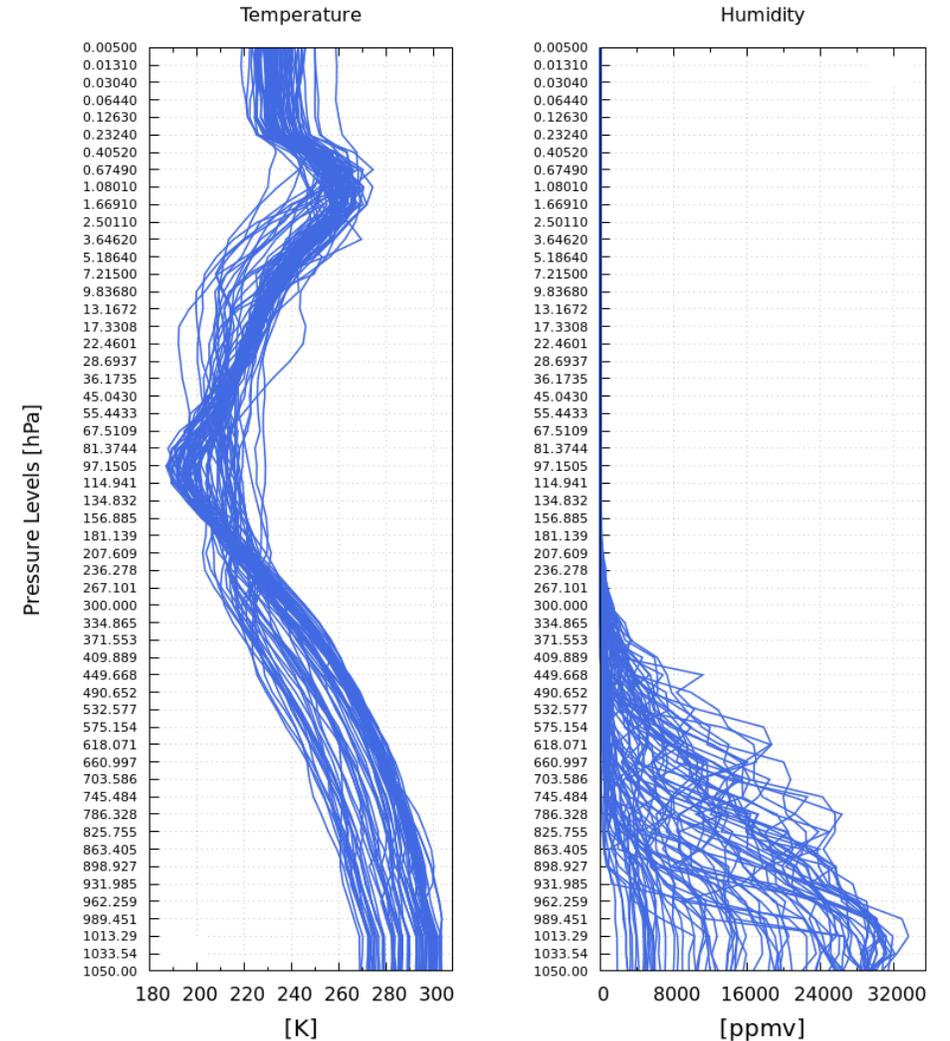

**77 profiles representative of different atmospheric conditions**  
(typical and extreme cases)

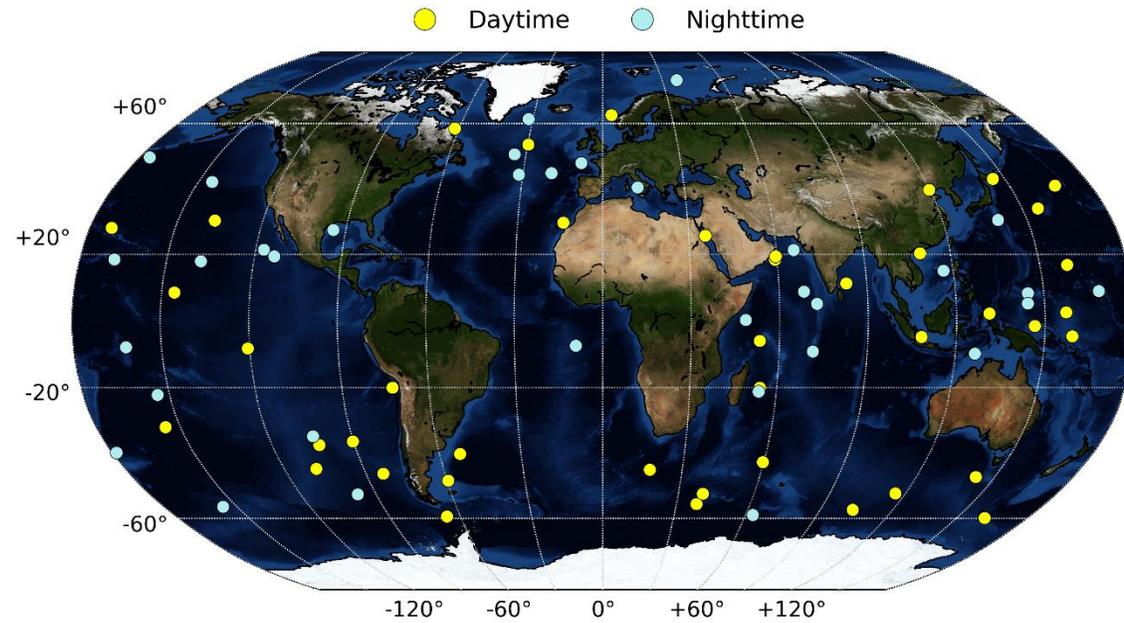

# Case Study for Channel Selection

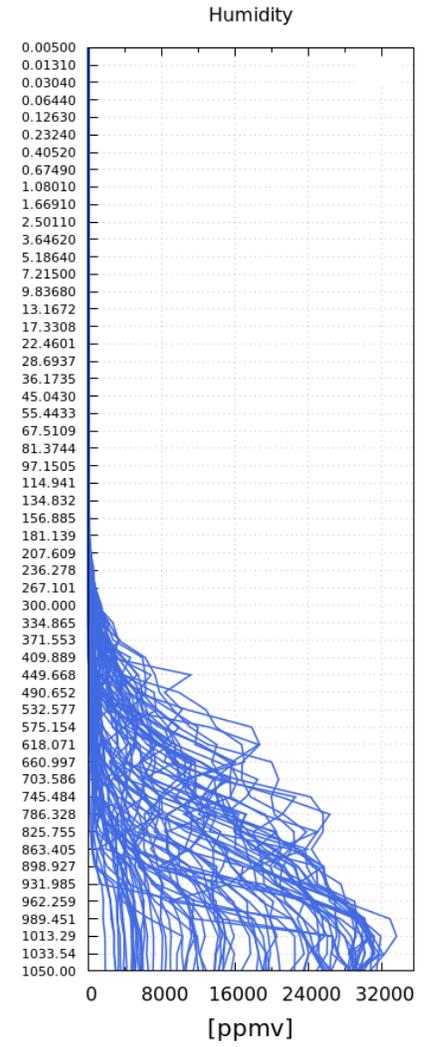

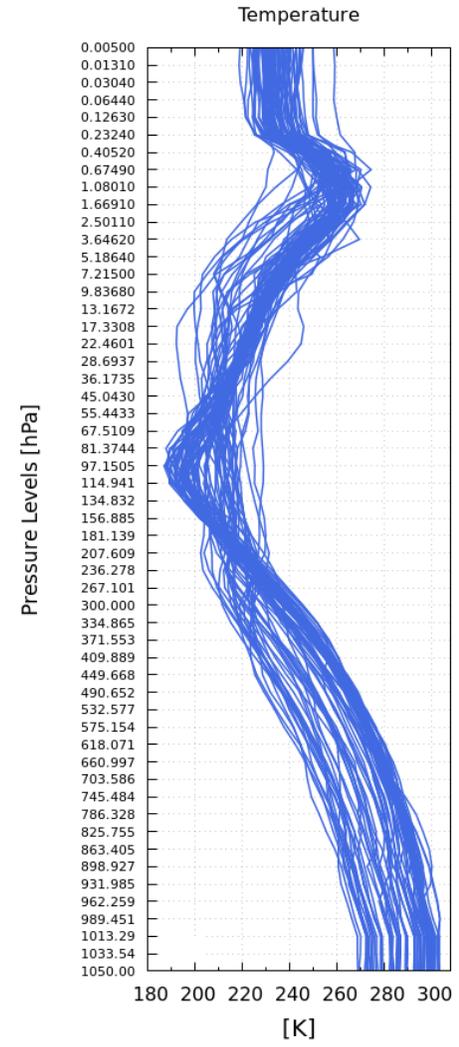

**77 profiles representative of different atmospheric conditions (typical and extreme cases)**

# Case Study for Channel Selection

**77 profiles representative of different atmospheric conditions (typical and extreme cases)**

# Methods

- ✓ A methodology relying on evaluating the impact of the addition of single channels on a figure of merit has been applied in order to determinate the optimal channel set [[Rodgers \(1996\)](#), [Rabier et al. \(2002\)](#)].
- ✓ The figure of merit chosen to implement the selection is the **Total DFS** (*Degrees of Freedom for the Signal*)

$$\text{DFS} := \text{Tr}(\mathbf{I} - \mathbf{A}\mathbf{B}^{-1}) = \text{Tr}(\mathbf{I}) - \text{Tr}[(\mathbf{I} + \mathbf{B}\mathbf{H}^T\mathbf{R}^{-1})^{-1}]$$

$$\text{DFS}_{\text{Tot}} = \text{DFS}_{\text{Temp}} + \text{DFS}_{\text{Hum}} + \text{DFS}_{\text{Skin Temp}}$$

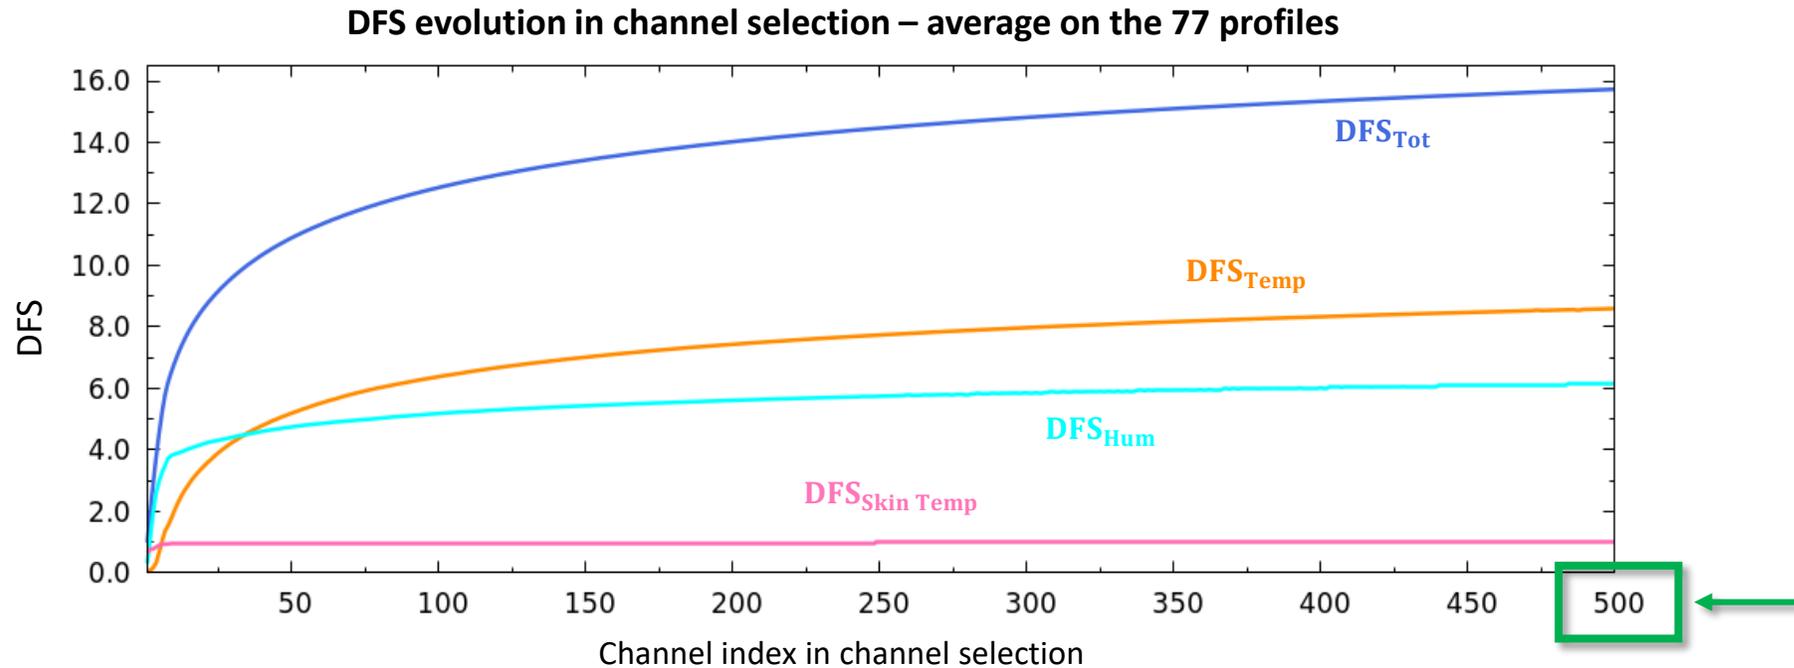

$\mathbf{A}$  = analysis-error covariance matrix

$\mathbf{B}$  = backg-error covariance matrix

$\mathbf{R}$  = analysis-error covariance matrix

$\mathbf{H}$  = matrix of the Jacobians

# Channel Selection

- ✓ The choice has been narrowed down to the first 500 channels selected on each profile (77 different channel selections).
- ✓ 500 is the amount of channels distributed for IASI (if the PC scores will be used, there is a good chance that this amount will be the same for IASI-NG).

# Channel Selection

We performed an analysis to evaluate the percentage of choice of the different channels:

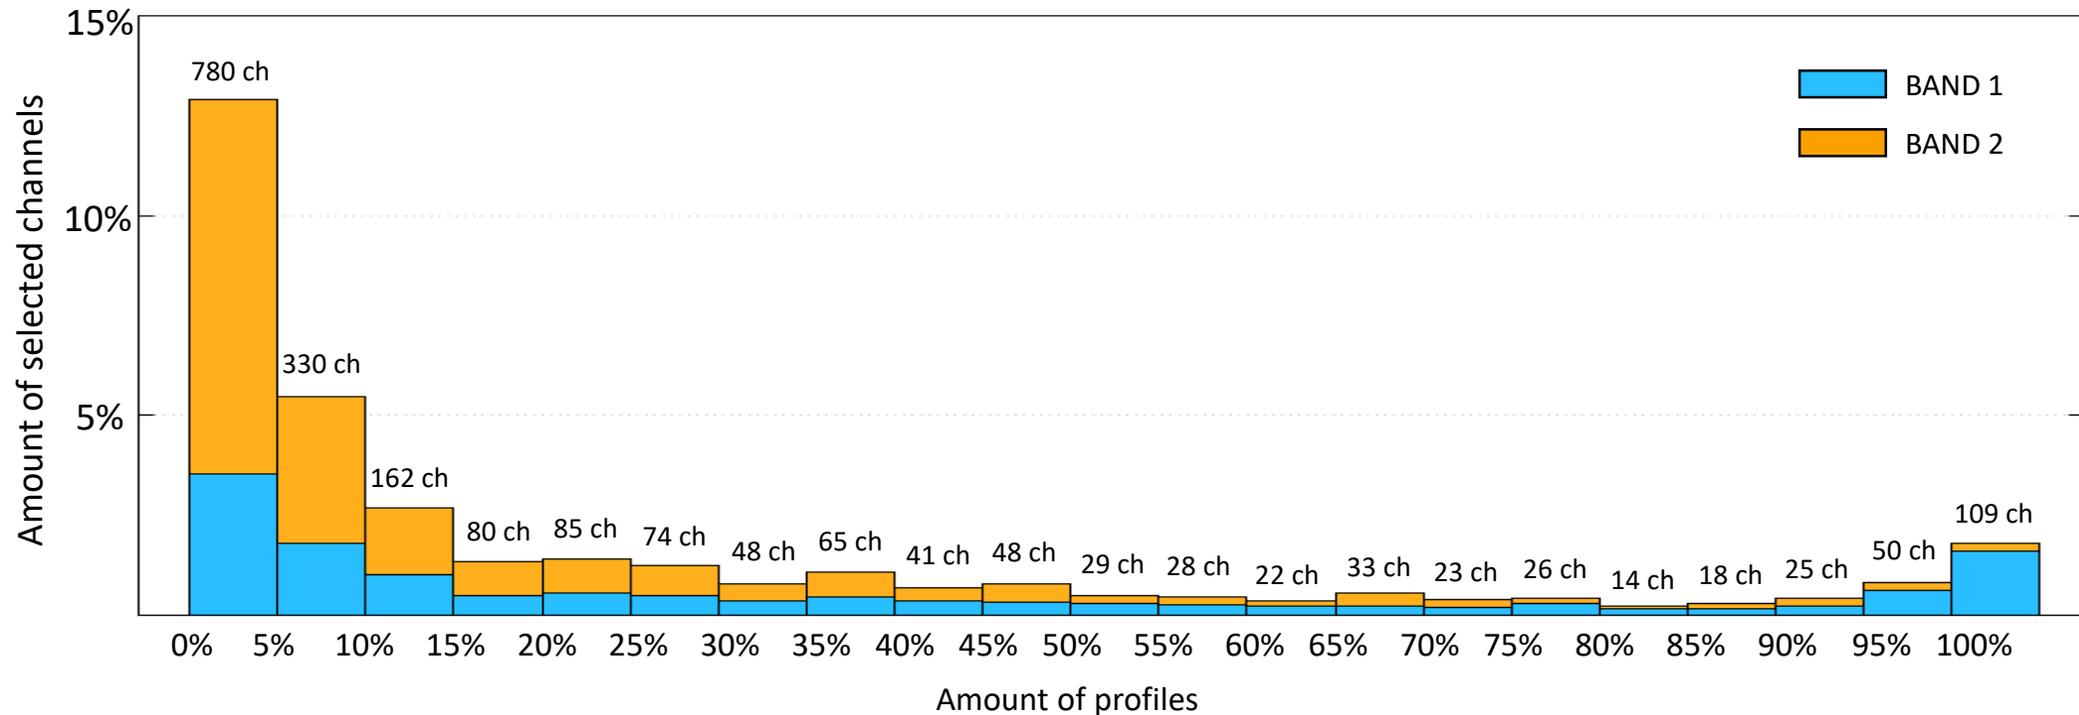

- ✓ **65%** of the total amount **of channels** is **never selected** (3959 out of 6049)

# Channel Selection

We performed an analysis to evaluate the percentage of choice of the different channels:

- ✓ **65%** of the total amount of **channels** is **never selected** (3959 out of 6049)
- ✓ **35%** (2090 channels) **selected at least once**

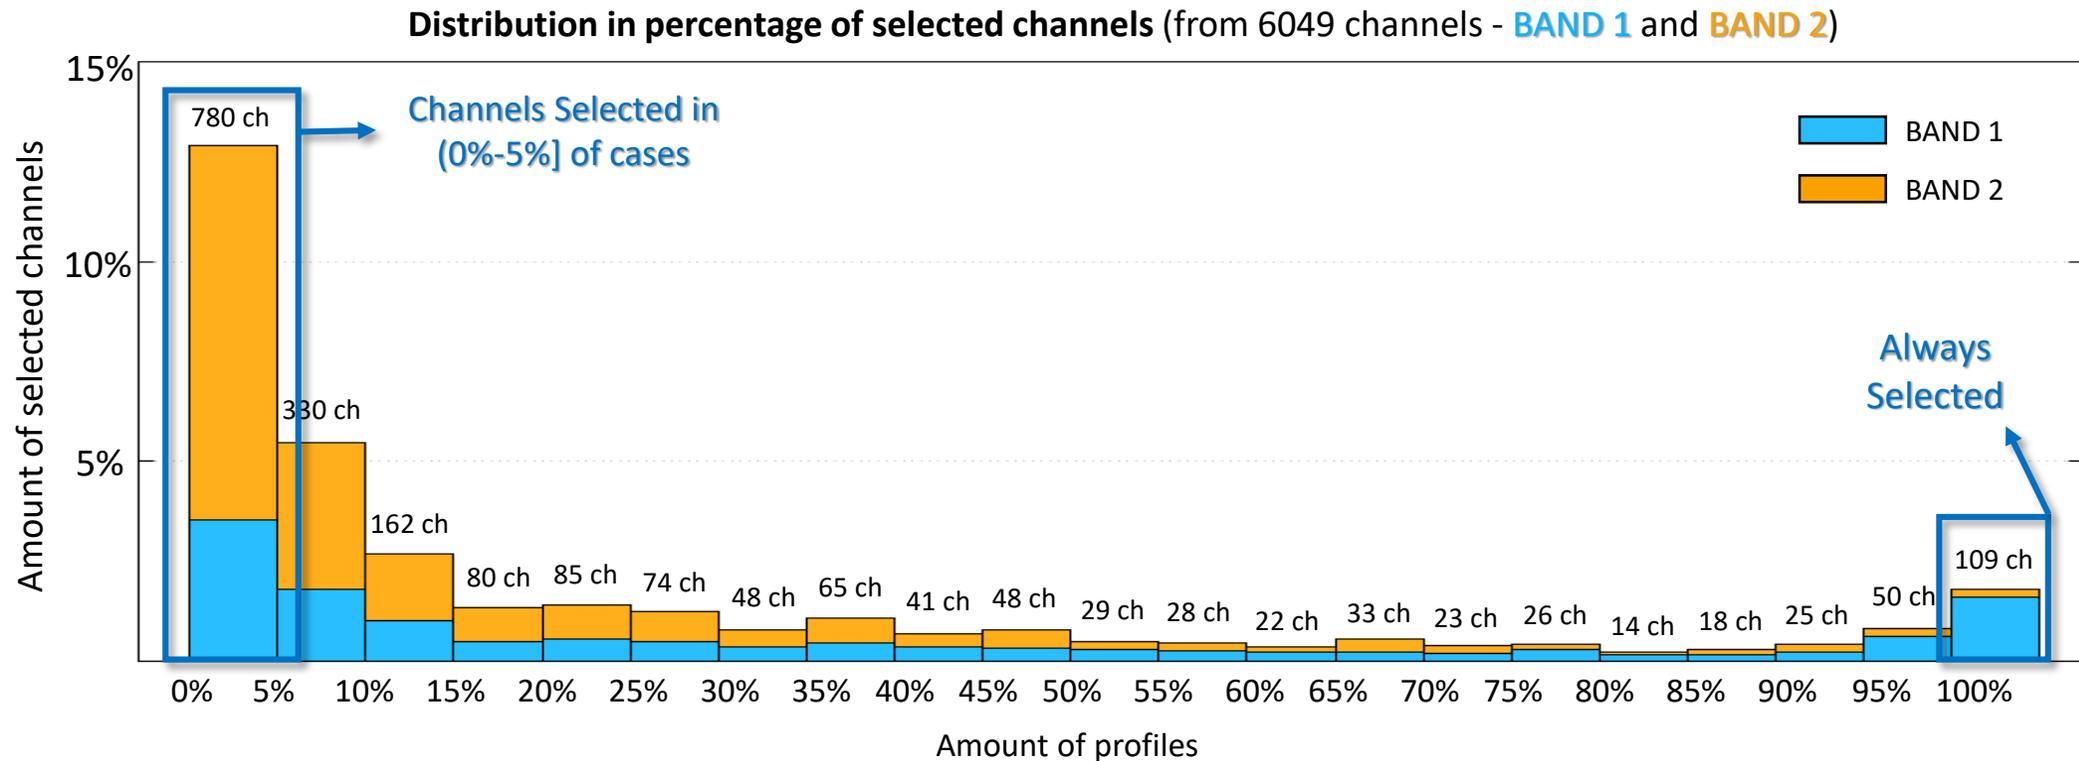

Distribution in percentage of selected channels (from 6049 channels - BAND 1 and BAND 2)

# Channel Selection

We performed an analysis to evaluate the percentage of choice of the different channels:

# ROI of Retrieval SD compared to the Background

The groups of channels just highlighted (selected on 77 profiles) have been used to perform 1D-Var experiments over the **6267 initial case study profiles**, in order to evaluate the impact of the selection.

# Channel Selection

# Conclusions and Future Works

- ✓ The selection we offer consists of 500 channels.
- ✓ This selection has been tested with very good results.
  
- Study bands and spectrum areas that we have not treated in this work (ozone, short waves, etc.)
- Bring the selected channels into the global model ARPEGE data assimilation, with all the observations available and over several weeks (OSSE)
- *Vittorioso et al.* in preparation for QJRMS
