Cloud optical properties: modeling and sensitivity study

- **Part 1**: Fast radiative transfer code for radiative transfer under cloudy condition
- **Part 2**: Sensitivity of high-spectral-resolution-infrared radiance to cirrus properties

Part 1: Fast radiative transfer code under cloudy condition

- Calculations of the single-scattering properties (extinction efficiency, absorption efficiency and asymmetry factor) of ice and water cloud particles
 - ▶
- Bulk optical properties of ice and water clouds, and parameterization
 - ▶
- Radiative transfer model under cloudy condition
 - ▶

Continued

- Database of albedo and transmissivity function for water and cirrus clouds and fast search code

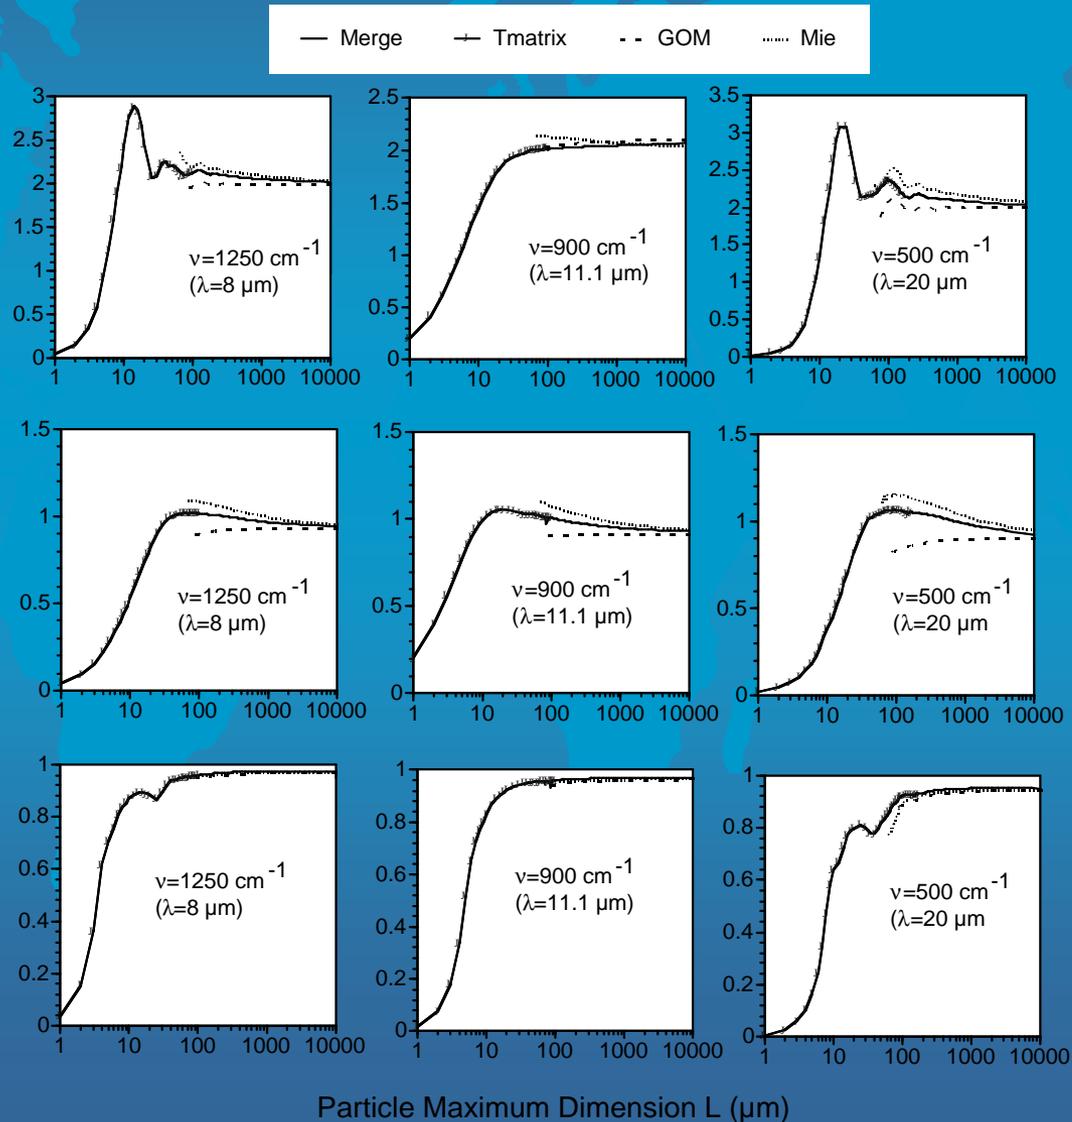

- Merge the fast model for clouds with clear sky model

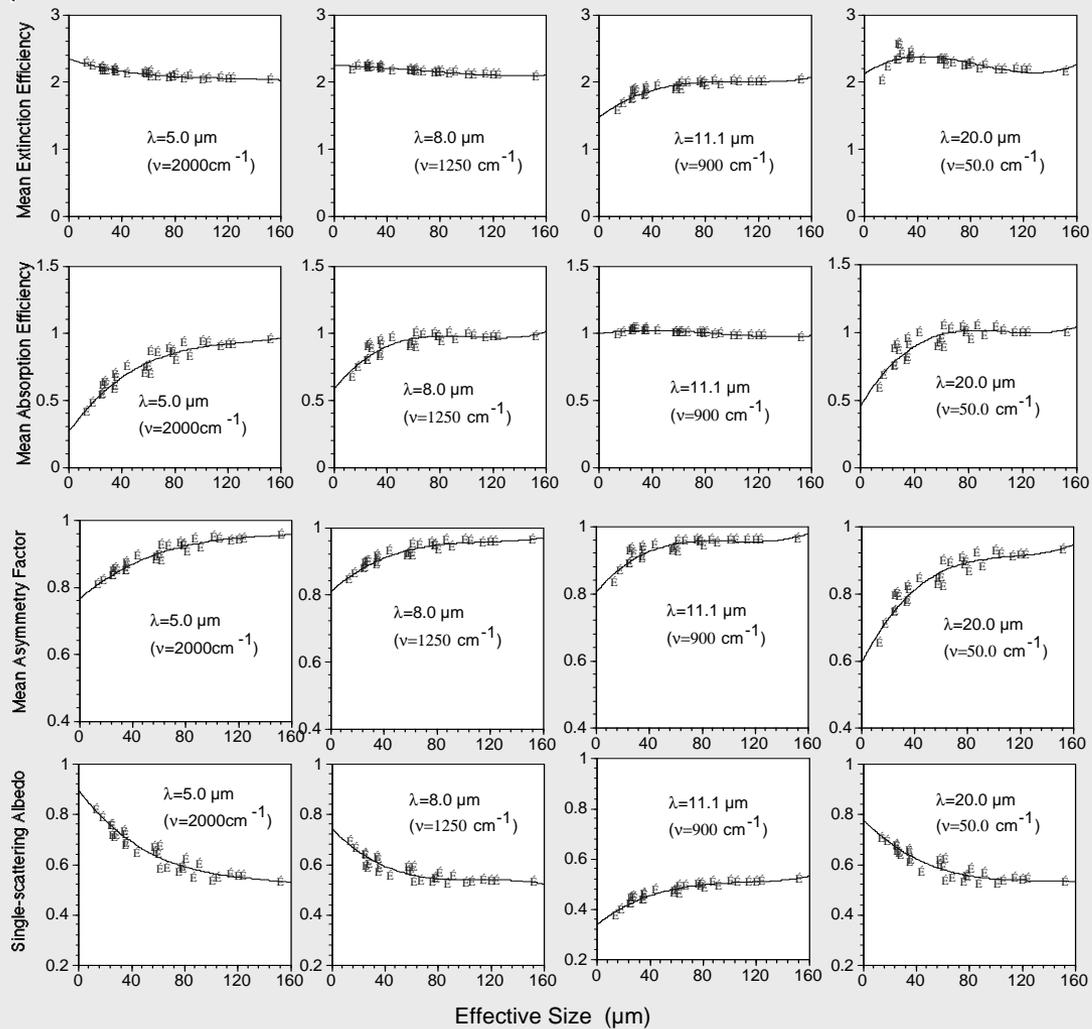

- Results

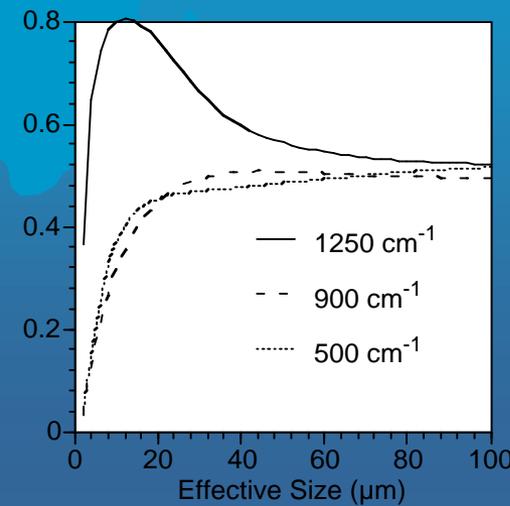

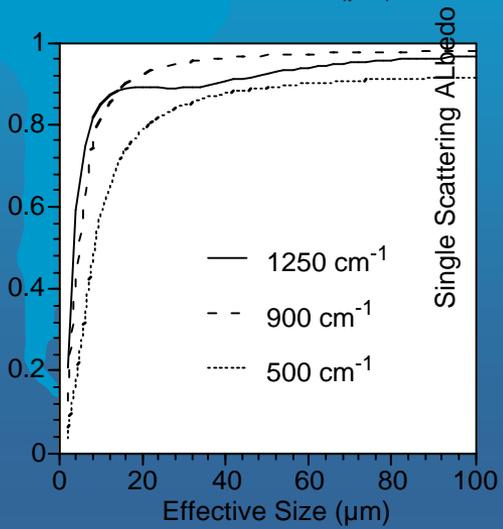

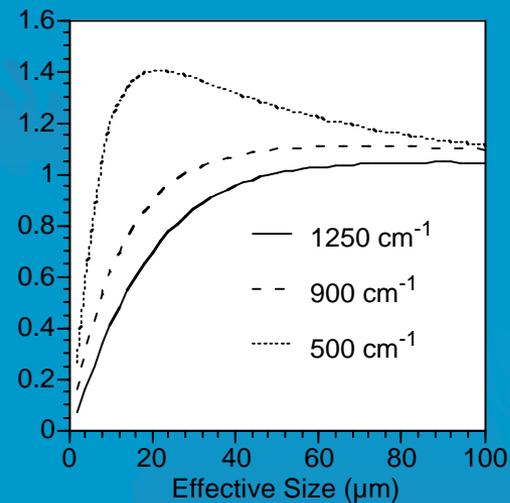

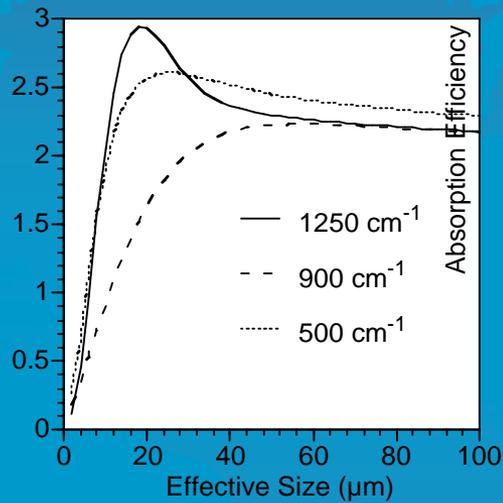

A composite method for the calculation of the single-scattering properties of ice crystals

Bulk optical properties of cirrus clouds and parameterization

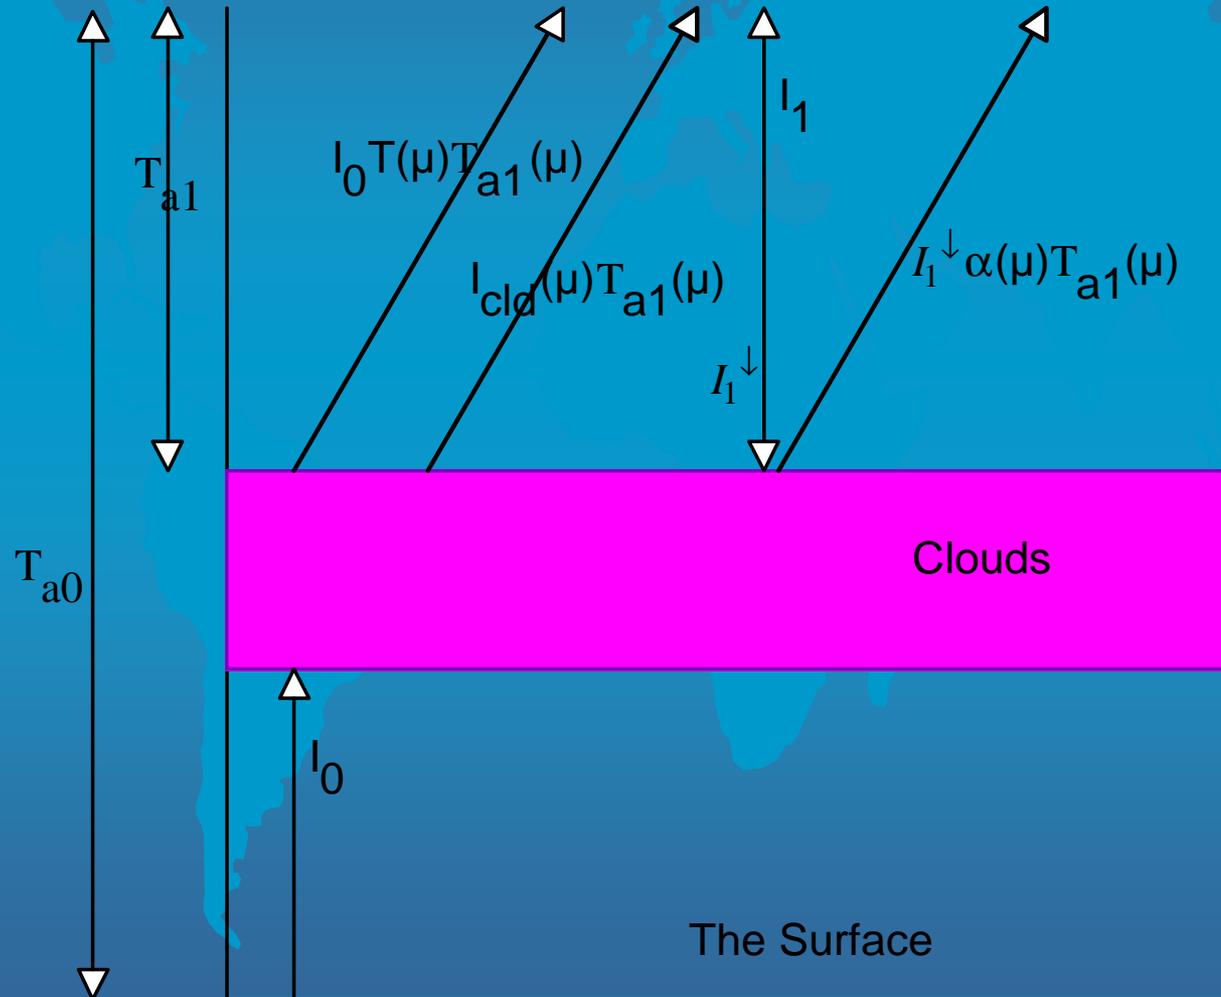

The mean extinction efficiency, absorption efficiency, asymmetry factor, and single-scattering albedo for water clouds

The scheme of radiative transfer for clouds

$$I_{top}(\mu) = I_0 T(\mu) T_{a1}(\mu) + I_{cld} T_{a1}(\mu) + I_1 + I_1^\downarrow \alpha(\mu) T_{a1}(\mu)$$

$$I_{top}(\mu) = I_0 T(\mu) T_{a1}(\mu) + I_{cld} T_{a1}(\mu) + I_1 + I_1^\downarrow \alpha(\mu) T_{a1}(\mu)$$

Where:

$$I_0 = B(t_s) T_{a0} + \int_{T_{a0}}^{T_{a1}} B(t) dT_a$$

$$I_1 = \int_{T_{a1}}^1 B(t) dT_a$$

$$I_{cld}(\mu) = [1 - R(\mu) - T(\mu)] * B(t_c)$$

$$I_1^\downarrow = \int_{T_{a1}}^1 B(t) \frac{T_{a1}}{T_a} dT_a$$

T_{a0} and T_{a1} are clear sky atmospheric transmission from the out space to the surface and to cloud top, respectively.

Database of albedo and transmissivity function for water and ice clouds

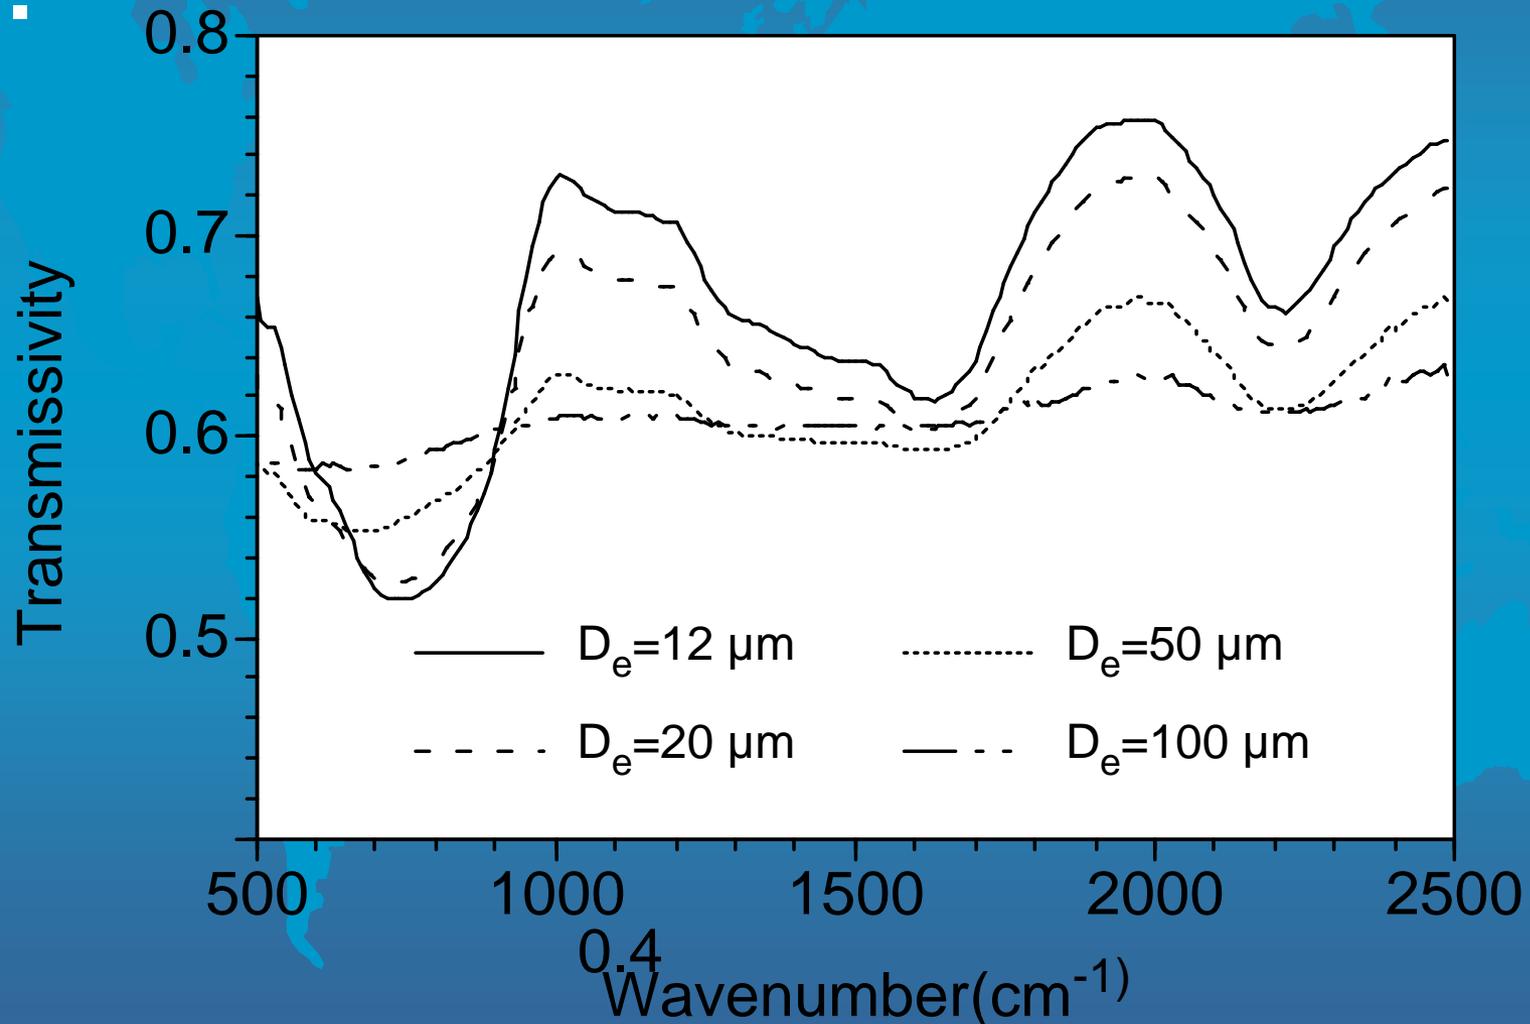

For ice clouds:

- ✓ Optical thickness: 0.04-50
- ✓ Effective size: 10-157 μm
- ✓ Zenith angle: (0-80°)
- ✓ Wavenumber:(500-2500 cm^{-1})

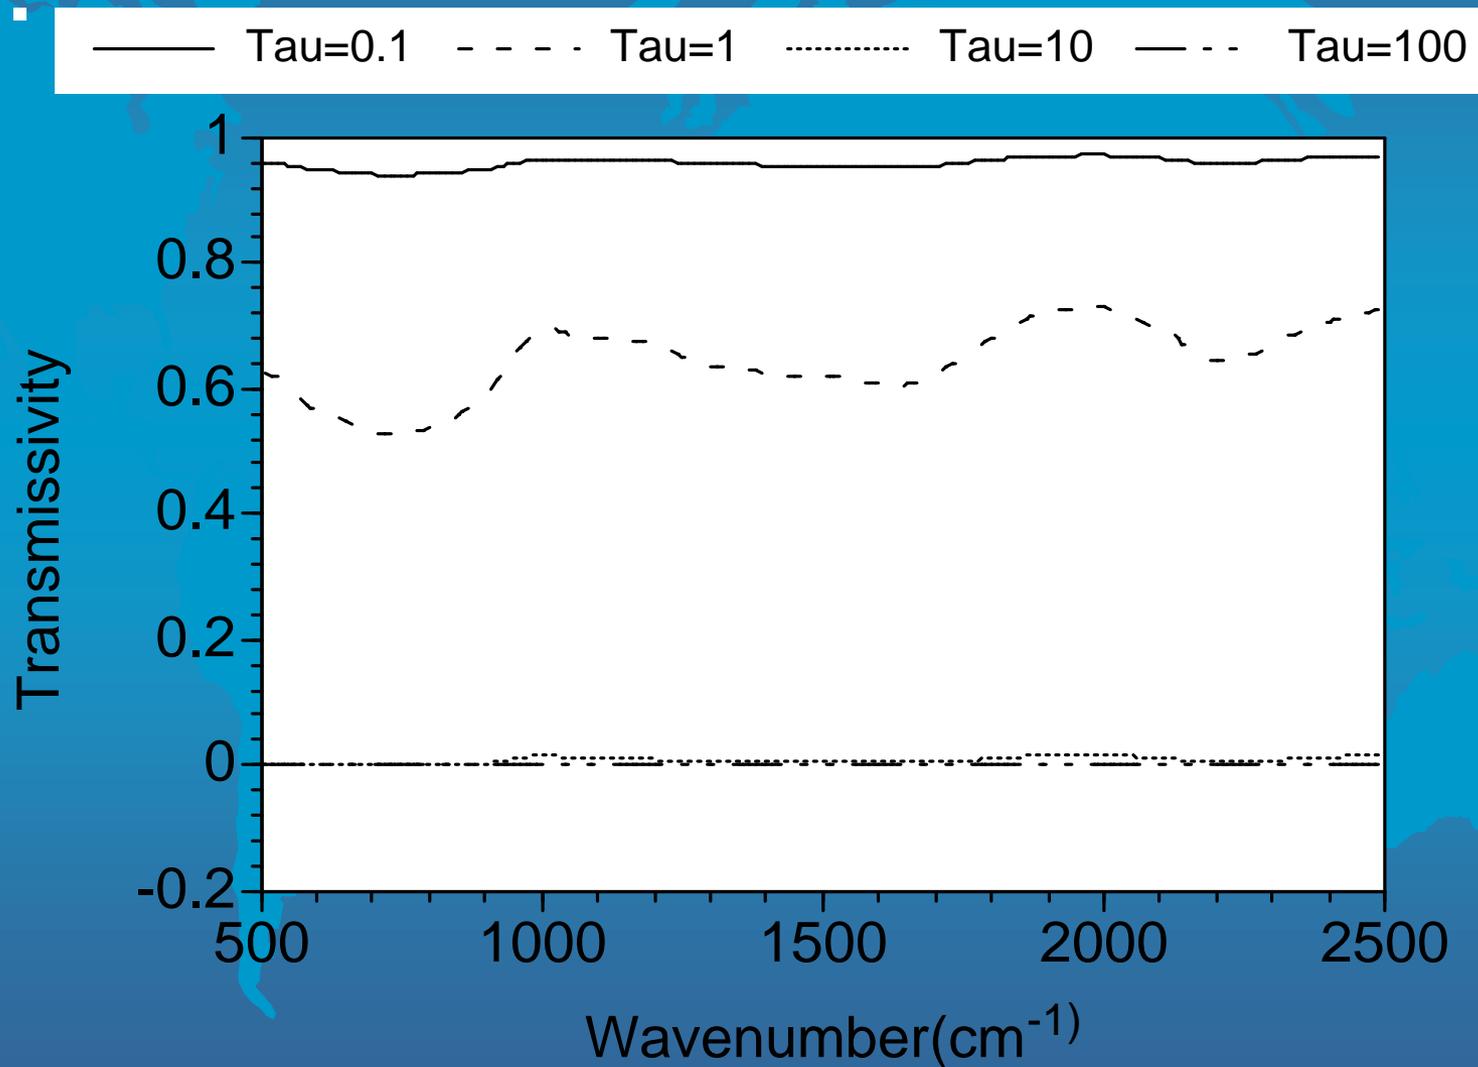

For water clouds:

- ✓ Optical thickness: 0.06-150
- ✓ Effective size: 2-20 μm
- ✓ Zenith angle: (0-80°)
- ✓ Wavenumber:(500-2500 cm^{-1})

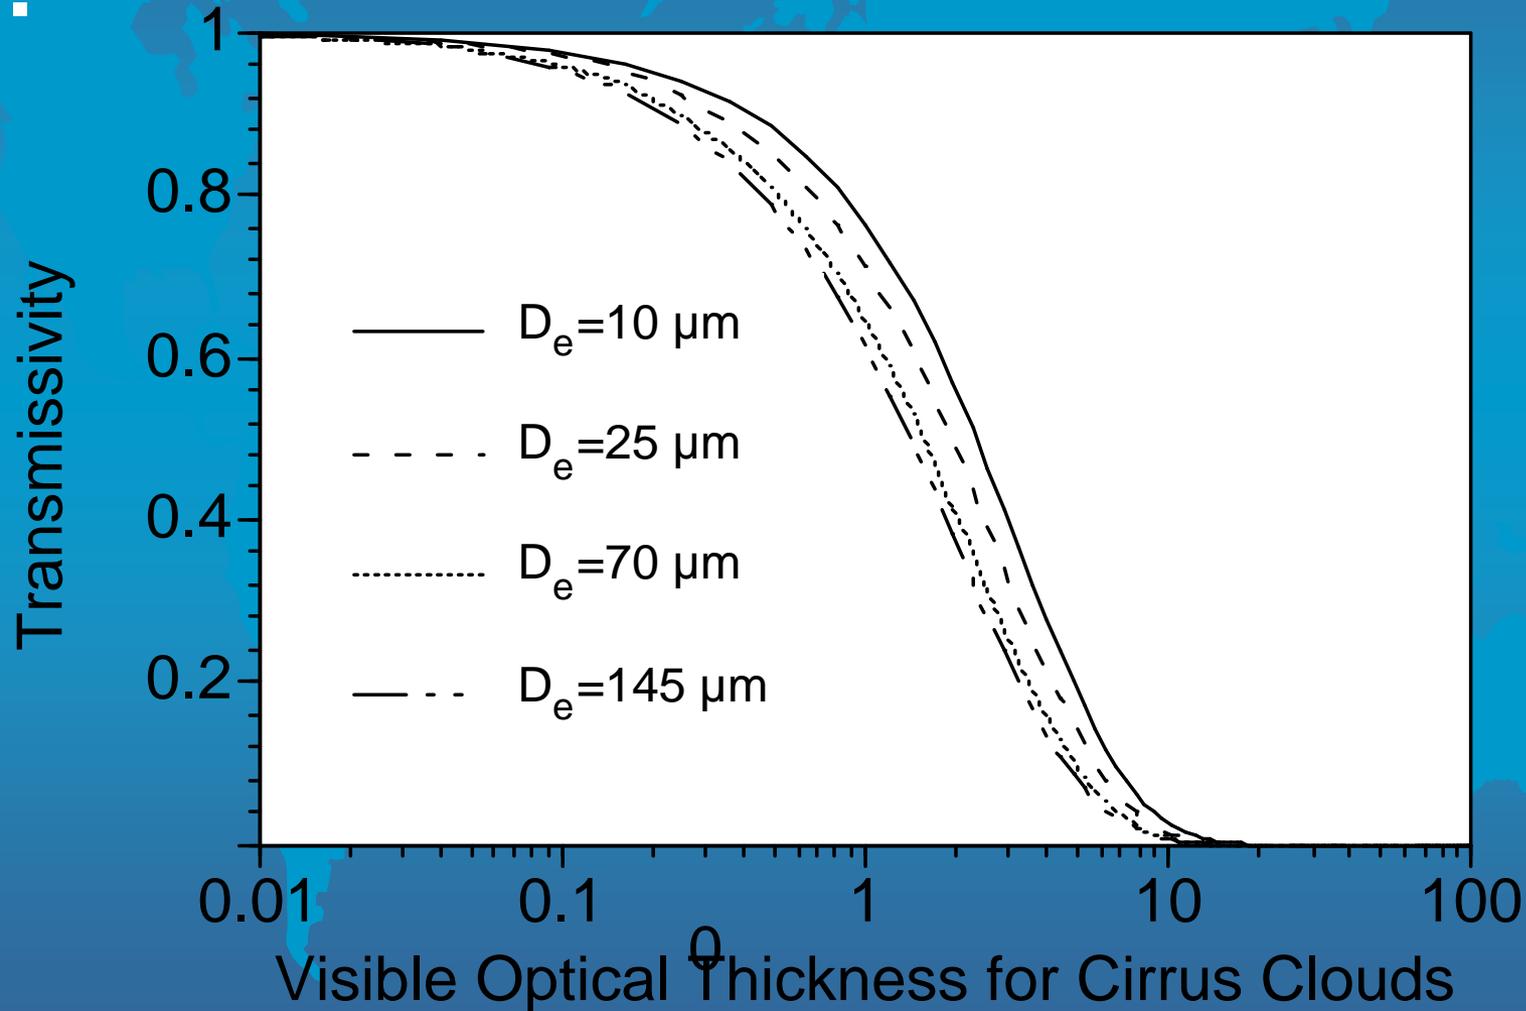

Transmissivity vs. wavenumber for 4 effective sizes (cirrus cloud, $\text{Tau}=1.0$)

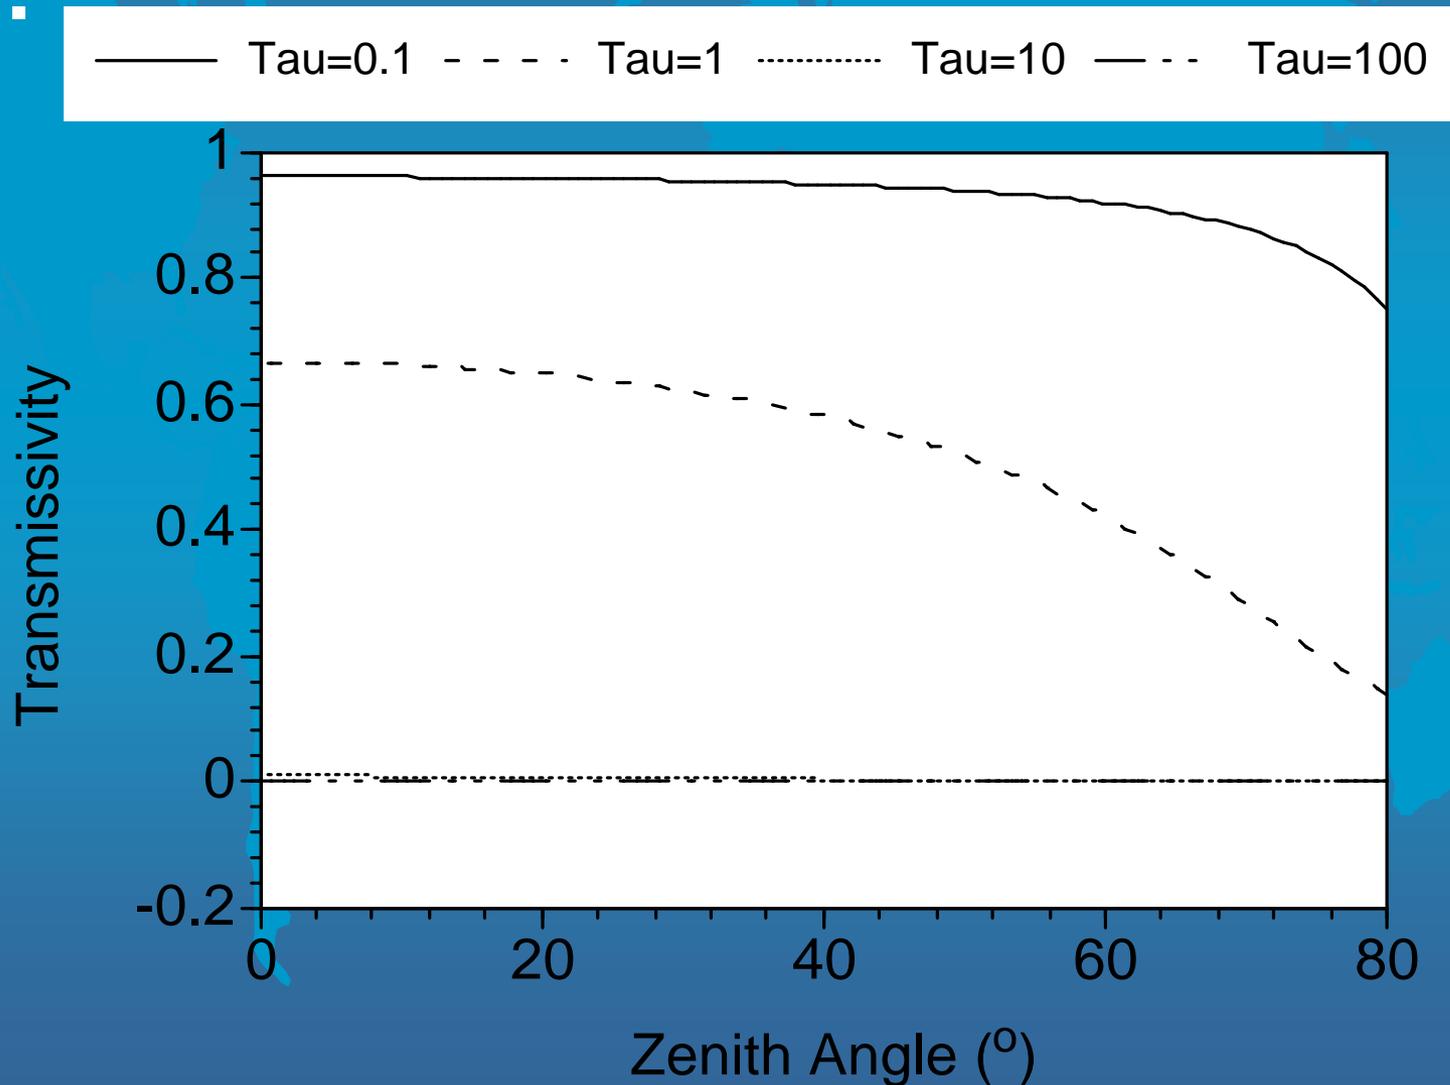

Transmissivity vs. wavenumber for 4 optical thicknesses (ice cloud, $D_{ei}=50\mu\text{m}$)

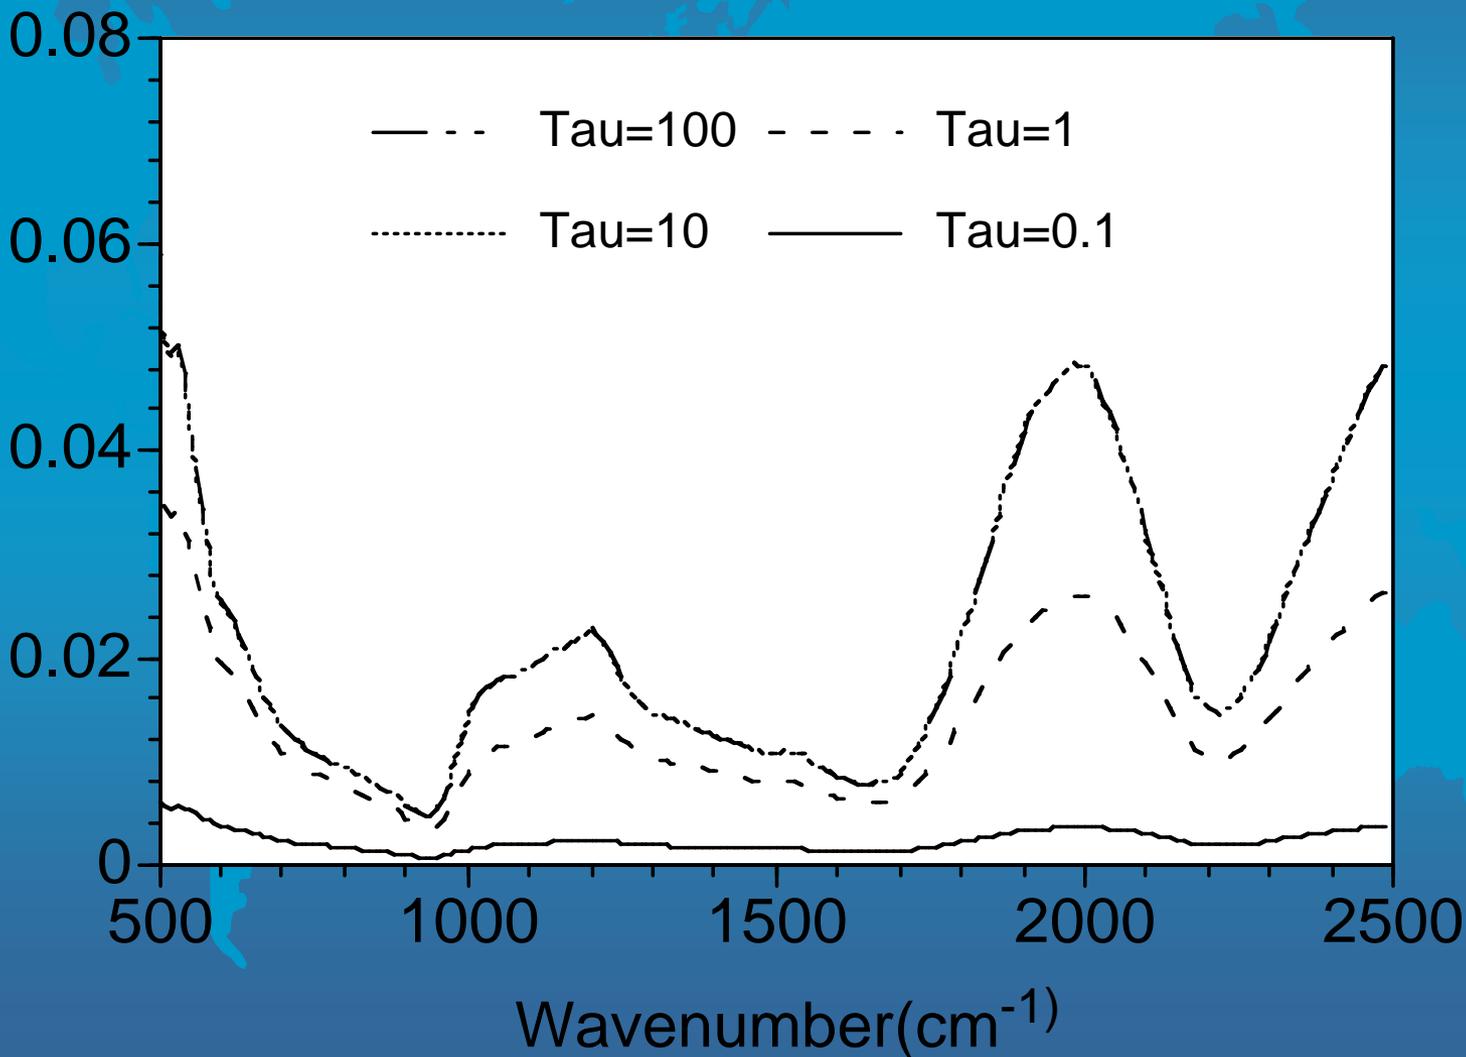

Transmissivity vs. optical thickness for 4 effective sizes (cirrus cloud, $\lambda=8\mu\text{m}$)

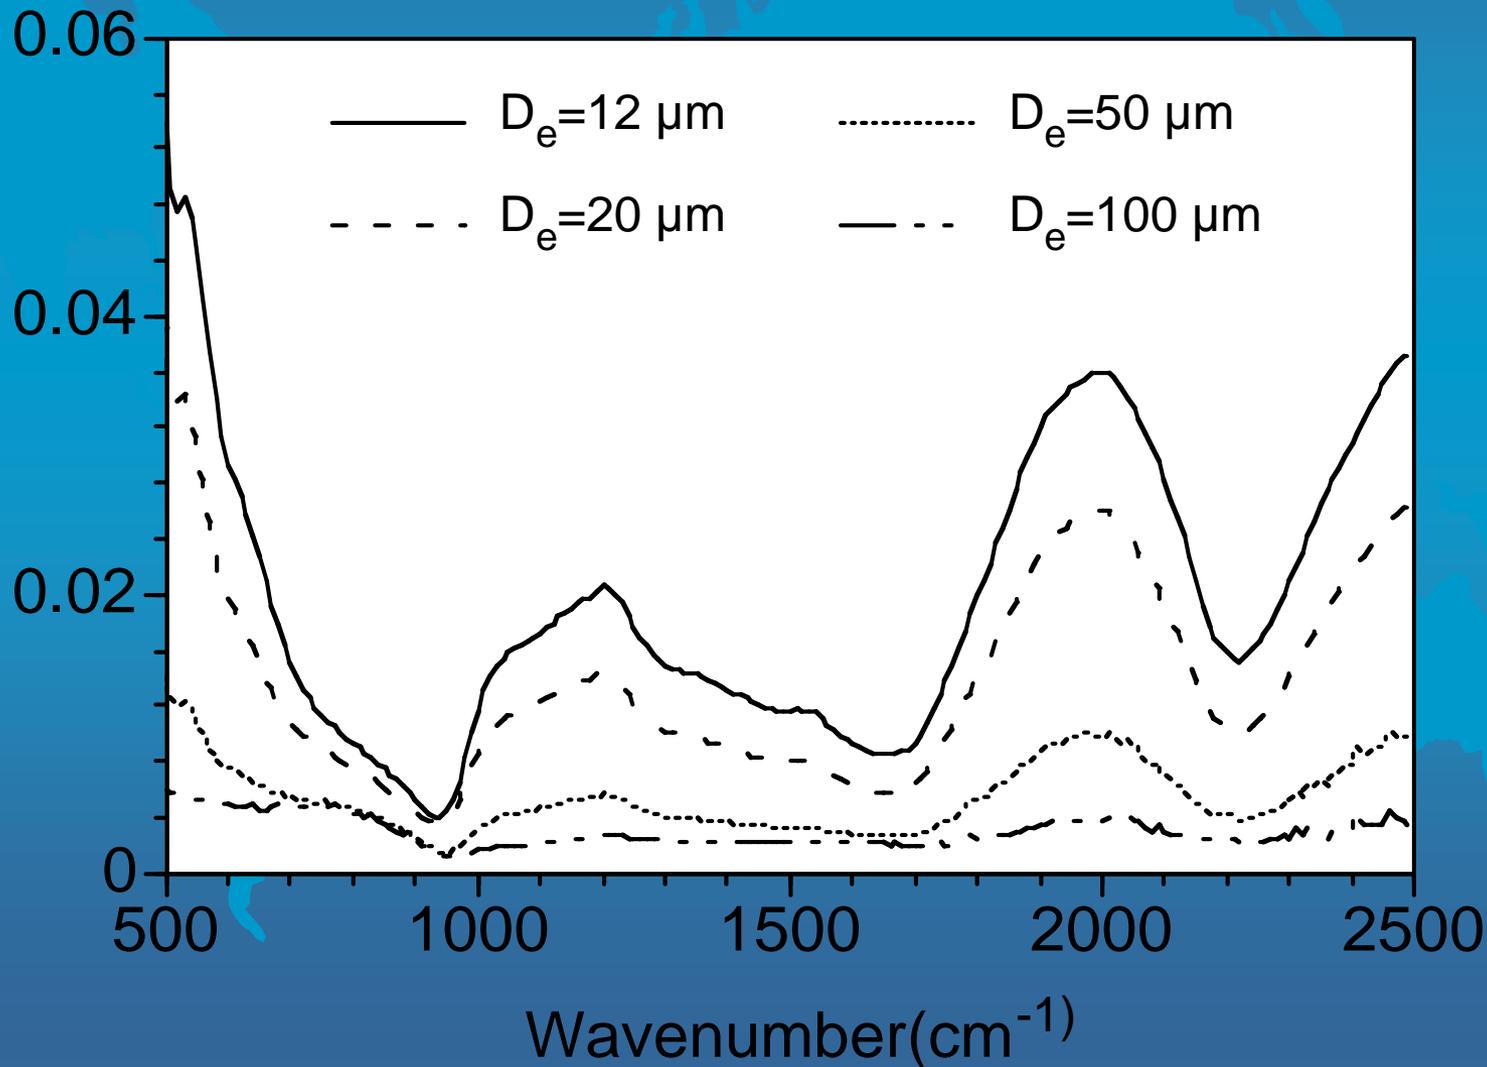

The transmissivity function vs. zenith angle at 4 optical thicknesses for ice clouds

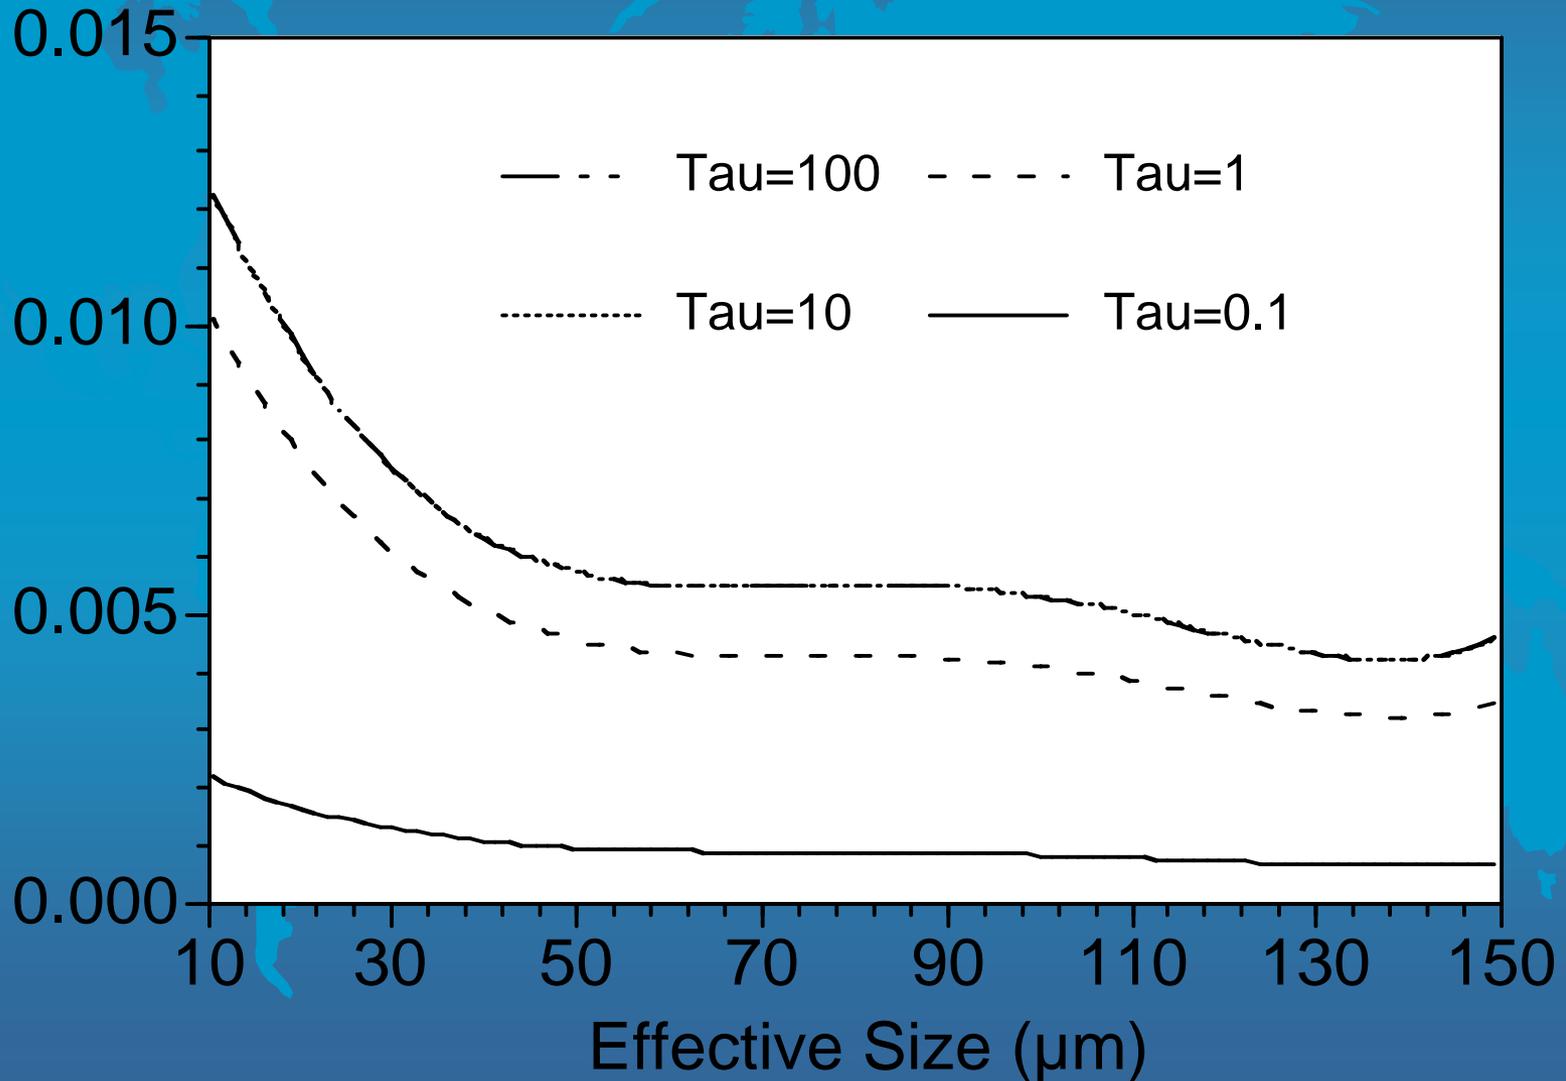

Albedo vs. wavenumber for 4 optical thicknesses (cirrus cloud)

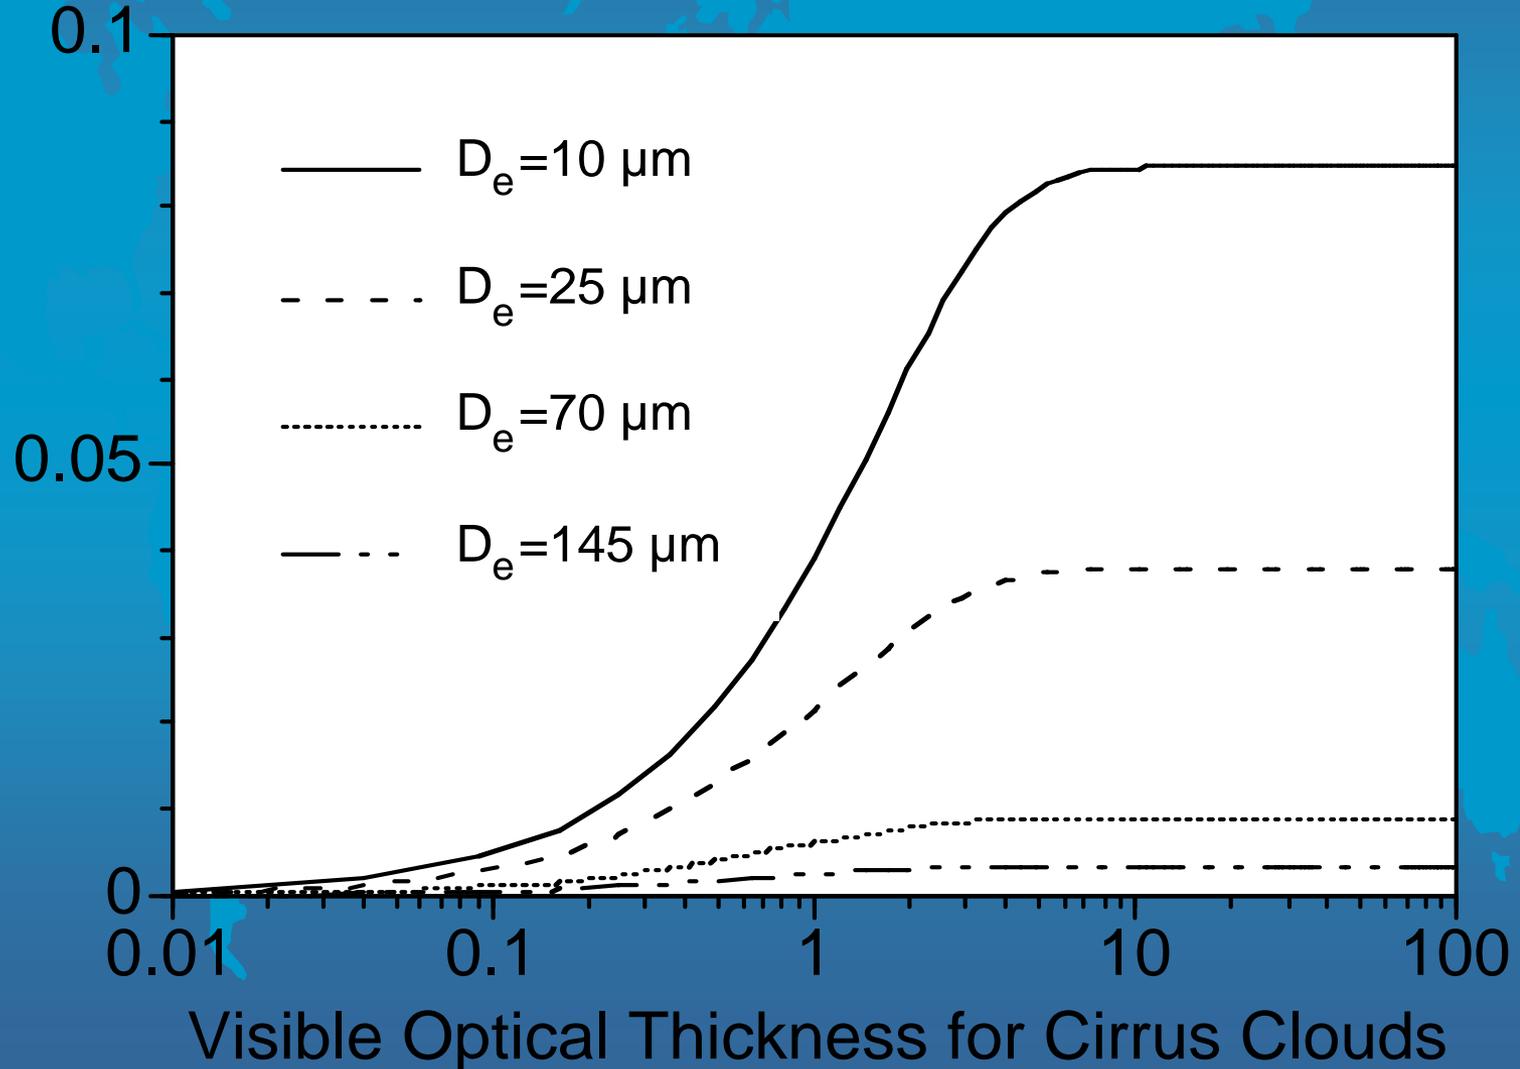

Albedo vs. wavenumber for 4 effective sizes (cirrus cloud)

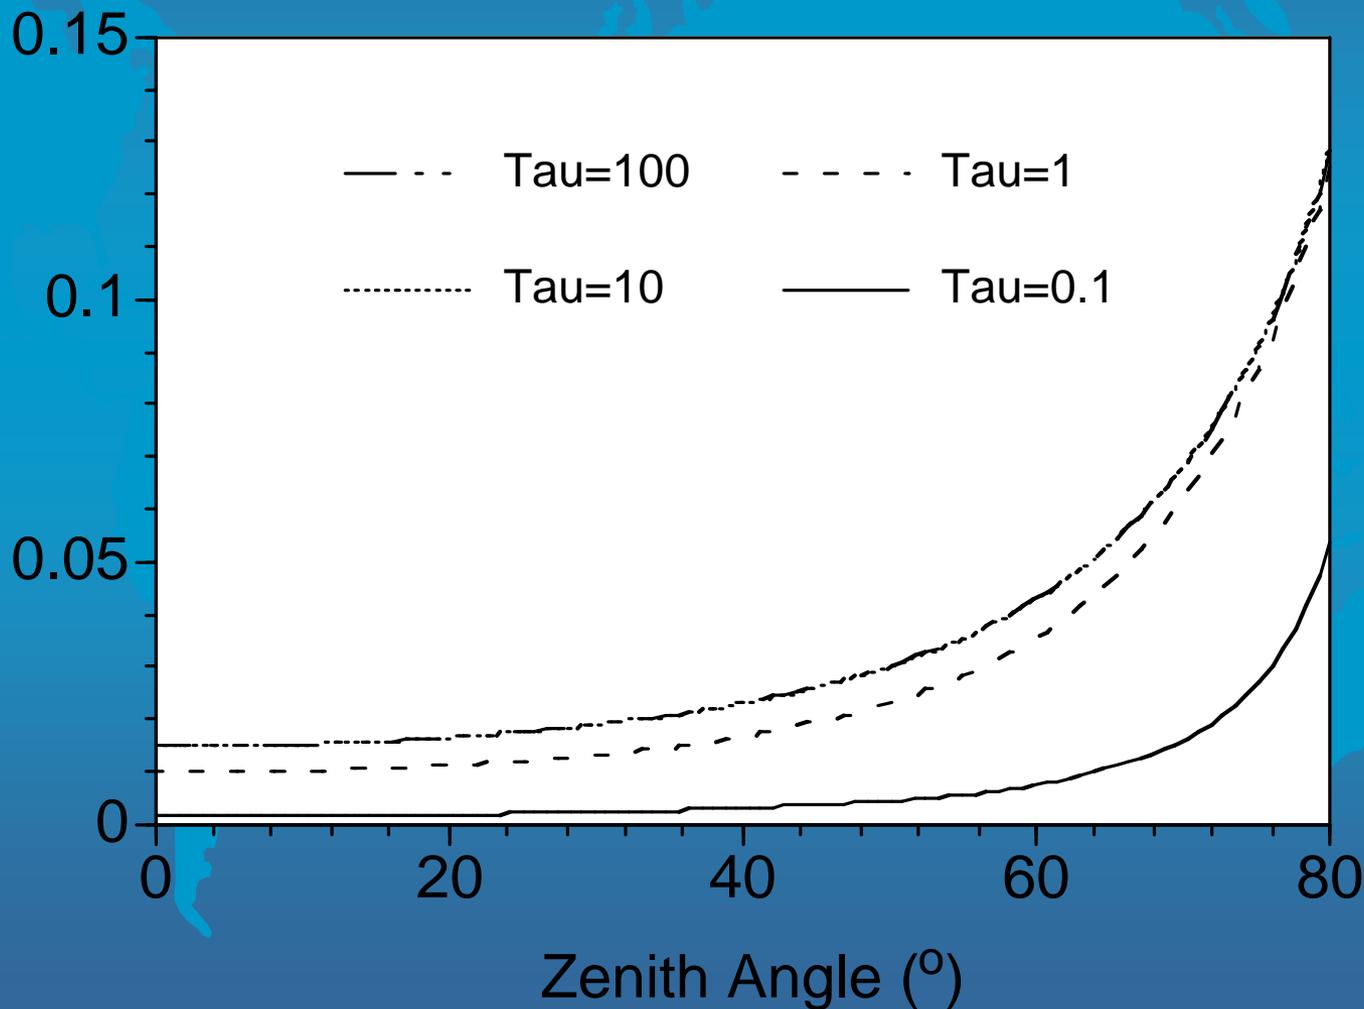

Albedo vs. effective size for 4 optical thicknesses (cirrus cloud, $\lambda=8\mu\text{m}$)

Albedo function vs. optical thicknesses for 4 effective sizes (cirrus cloud)

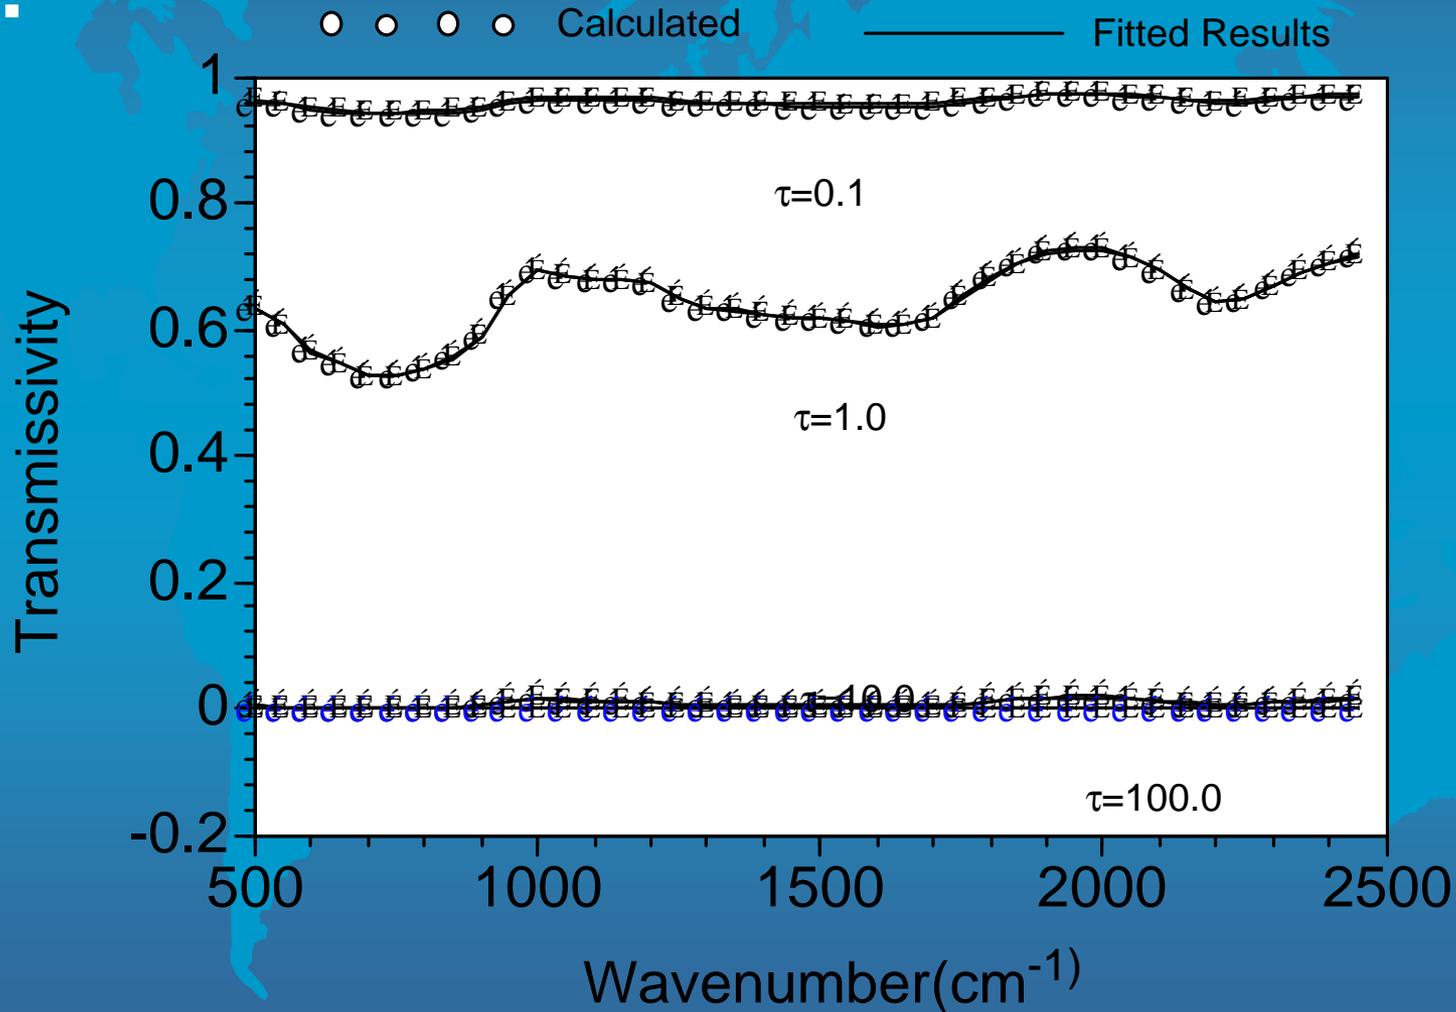

Albedo vs. zenith angle for 4 optical thicknesses (cirrus cloud)

Interpolate albedo and transmissivity from database

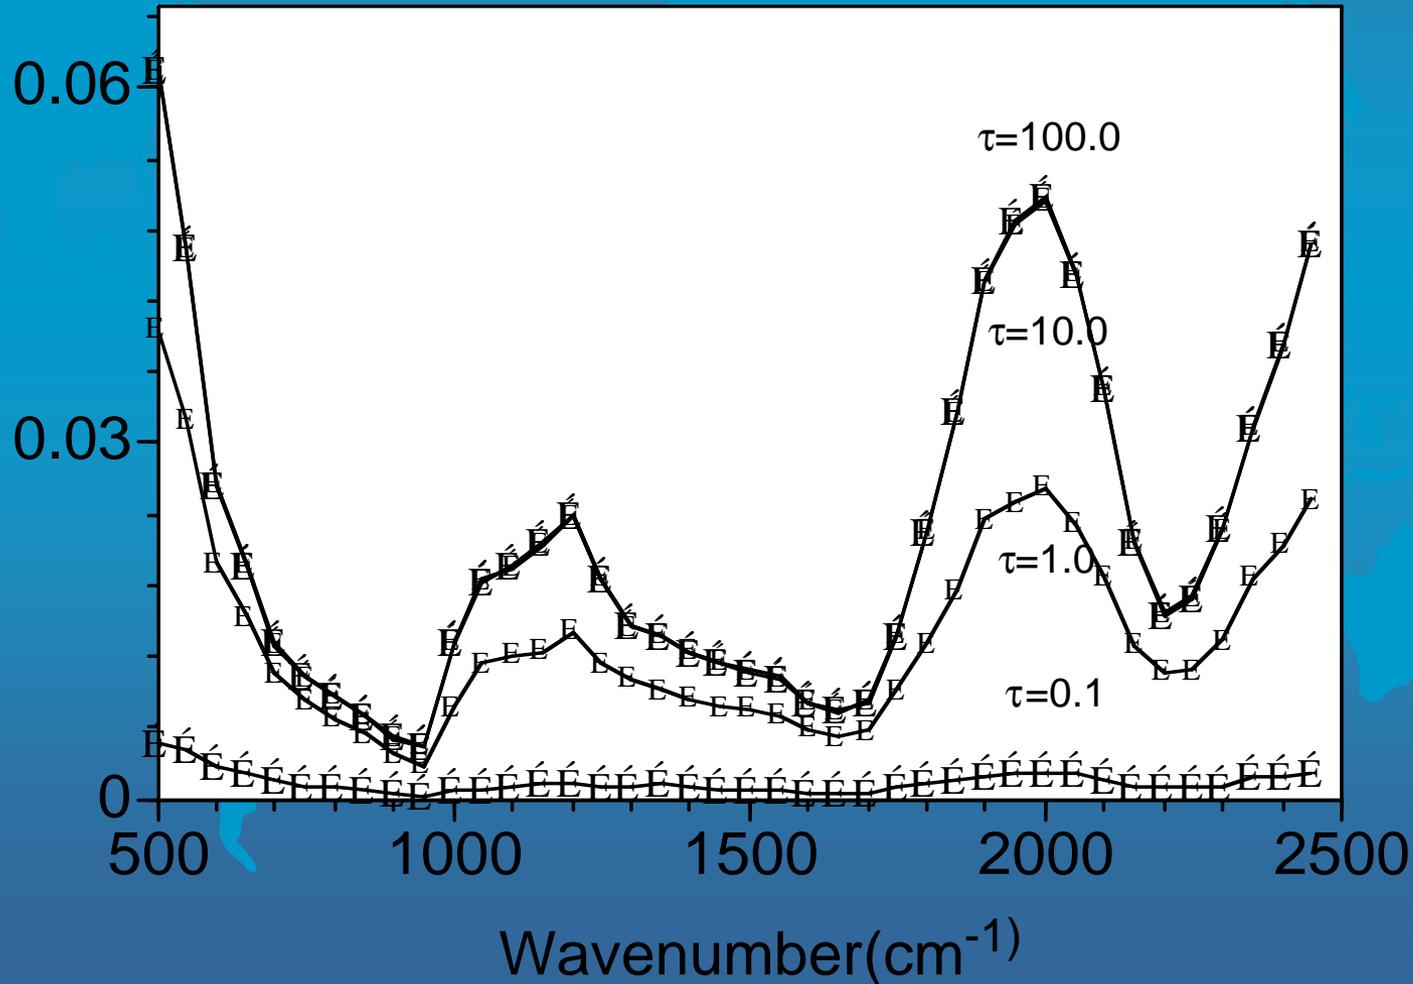

A code is developed to interpolate albedo and transmissivity from a pre-calculated database for given wavelength, zenith angle, effective sizes and optical thickness (cirrus and water clouds) by using two-dimensional (2D) polynomial fitting and 2D interpolation

Interpolate transmissivity of clouds from the pre-calculated database

Interpolate albedo of clouds from the pre-calculated database

○ ○ ○ ○ Calculated — Fitted Results

Merge the cloudy and clear-sky fast models

- We developed a computational package to compute the radiance at any atmospheric level for given profiles of clear-sky atmospheric optical thickness and temperature (which are from the clear sky fast model) and the parameters of clouds

Results

Accuracy

- The root-mean-square (RMS) difference between the fast model and DISORT is less than 0.5K, as illustrated in the [attached diagrams](#)

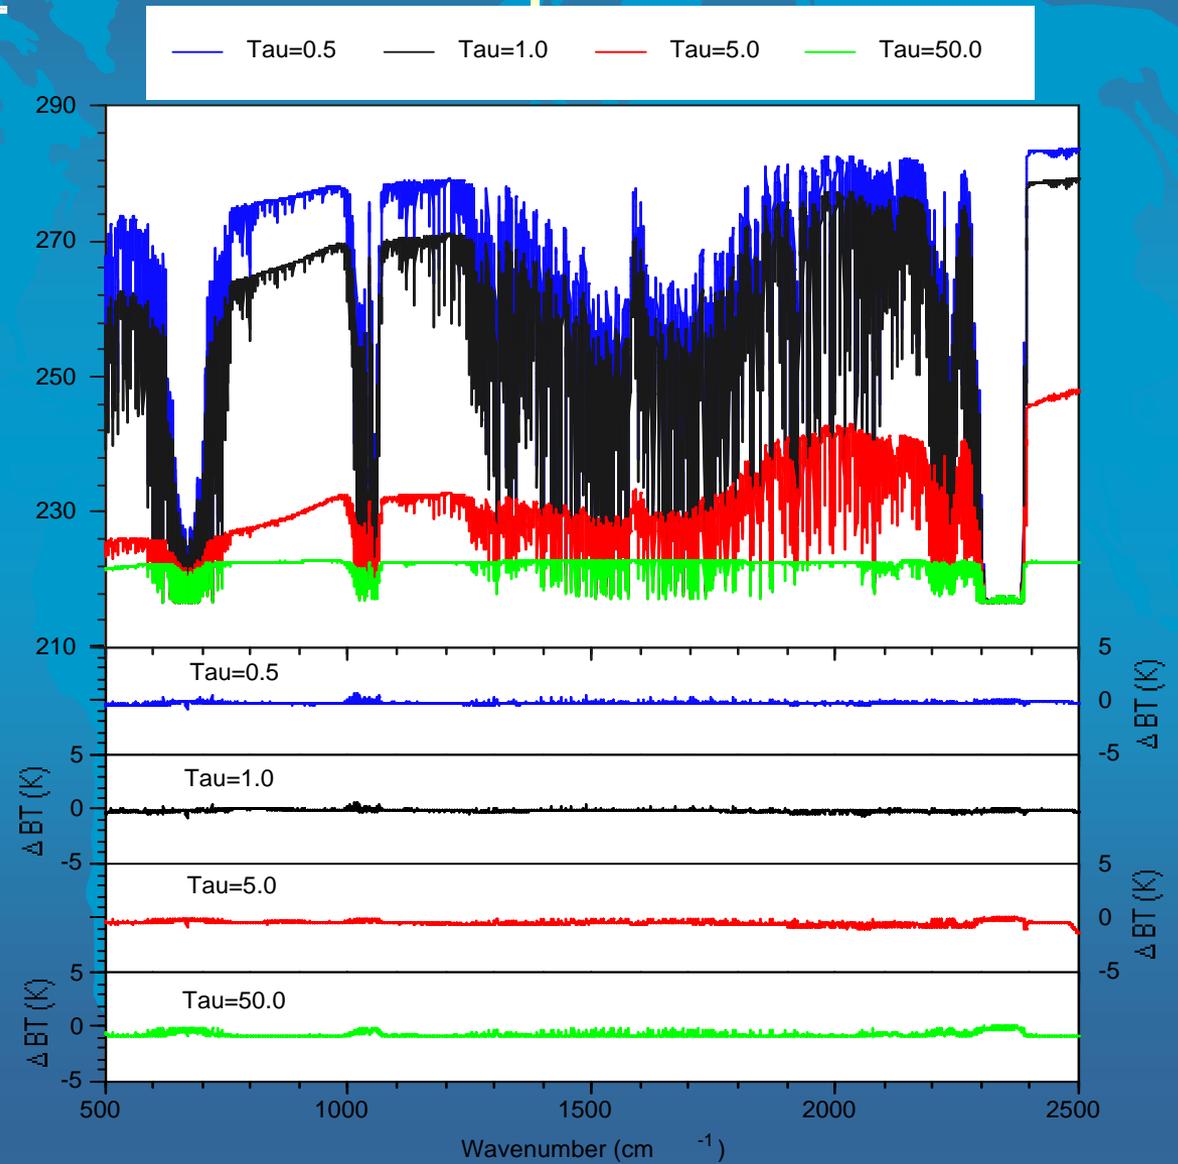

Speed:

- The computational speed of the fast model is approximately 1000 times faster than the DISORT model.

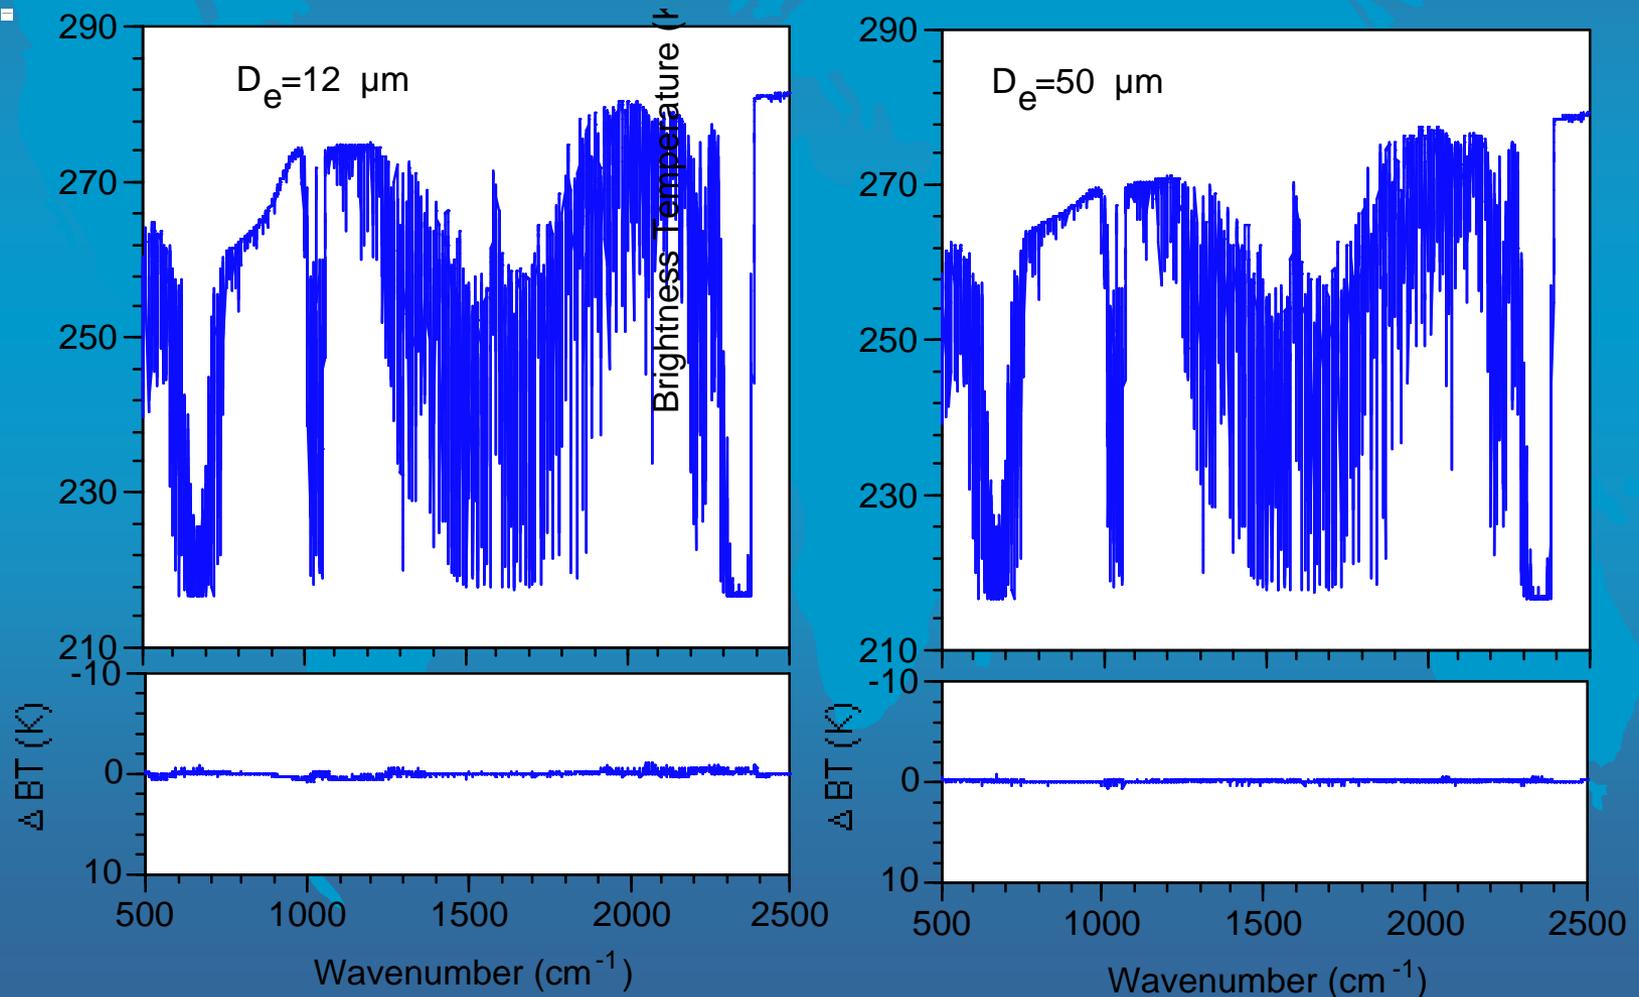

Test case: 8000 wavenumbers ($500\text{-}2500\text{cm}^{-1}$) and 100 layers atmosphere with single-layer clouds on Dell Precision 530 workstation. It takes 254s for DISORT whereas the fast model needs only 0.25s.

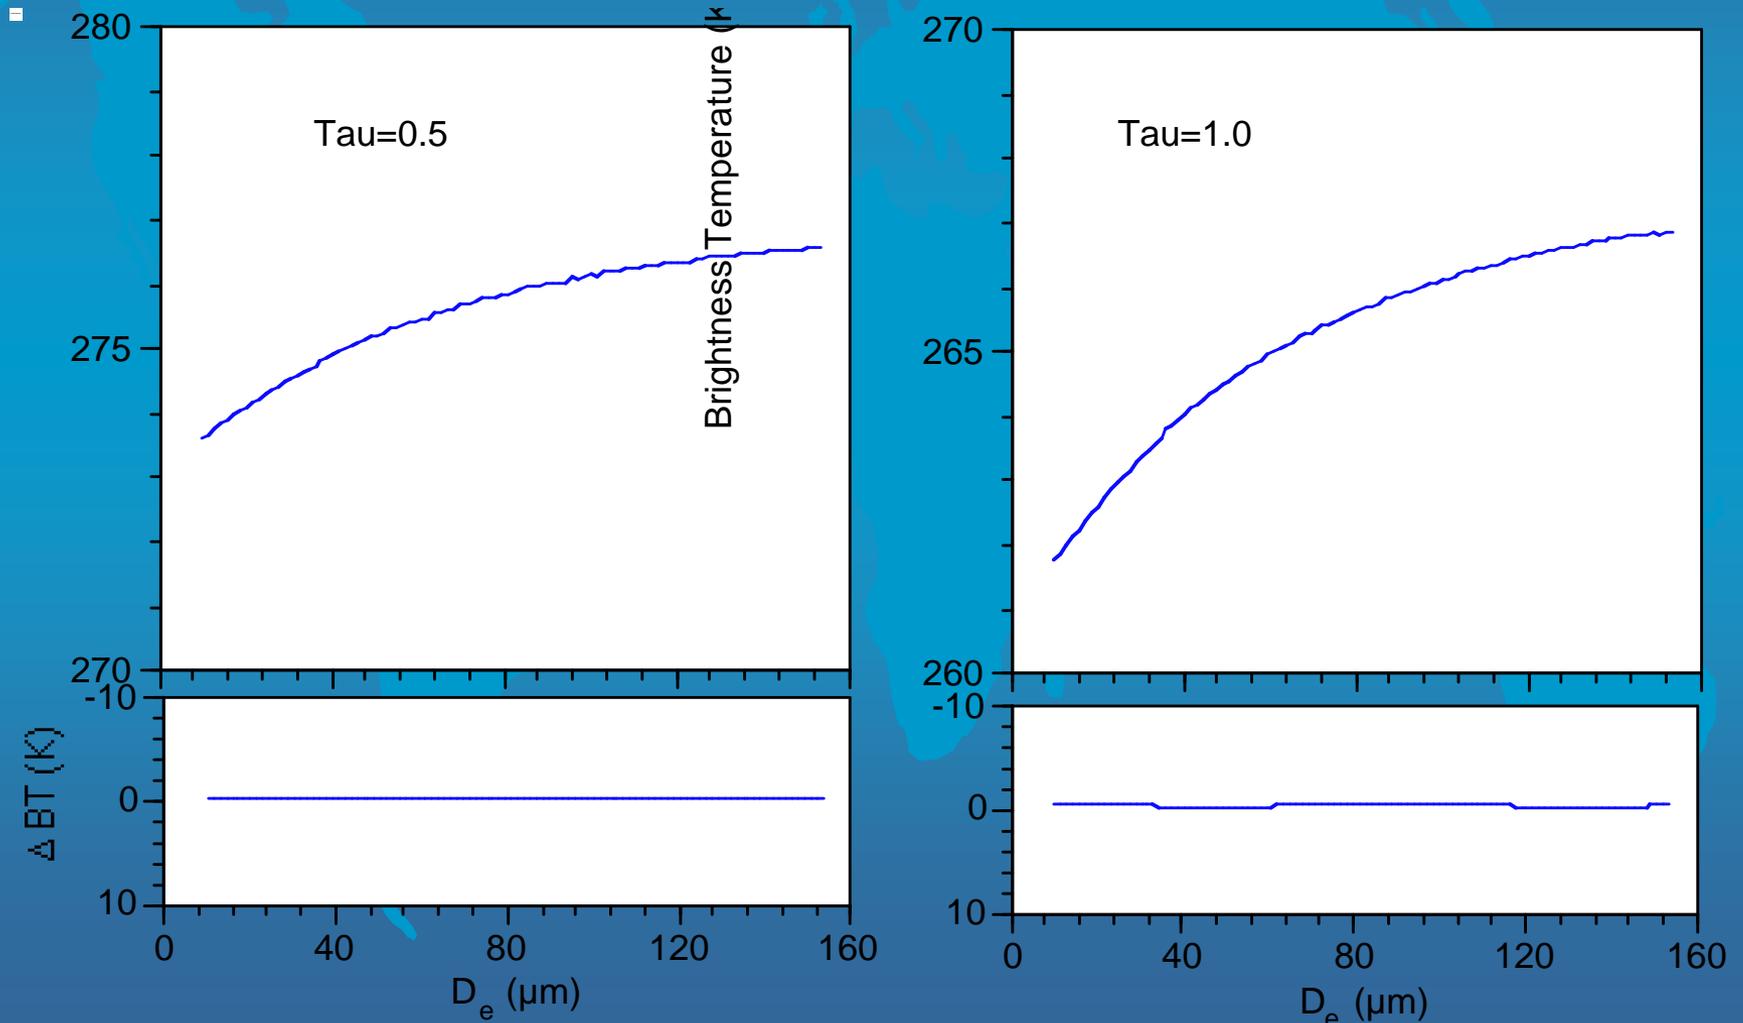

Spectra calculated by the fast model and the deviations compared with DISORT

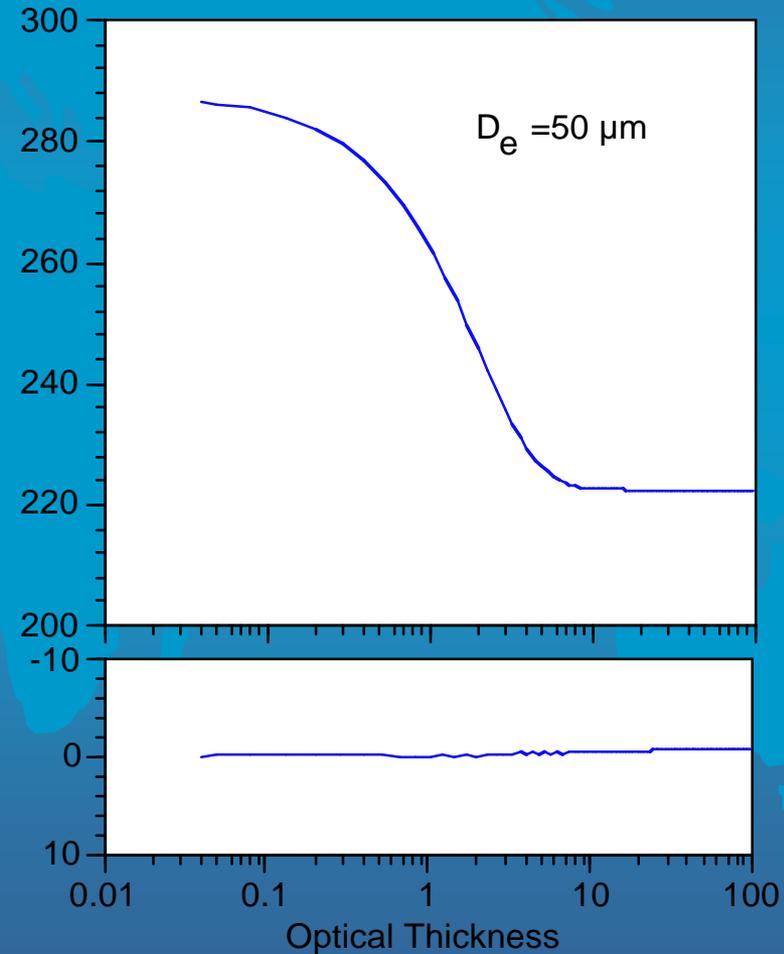

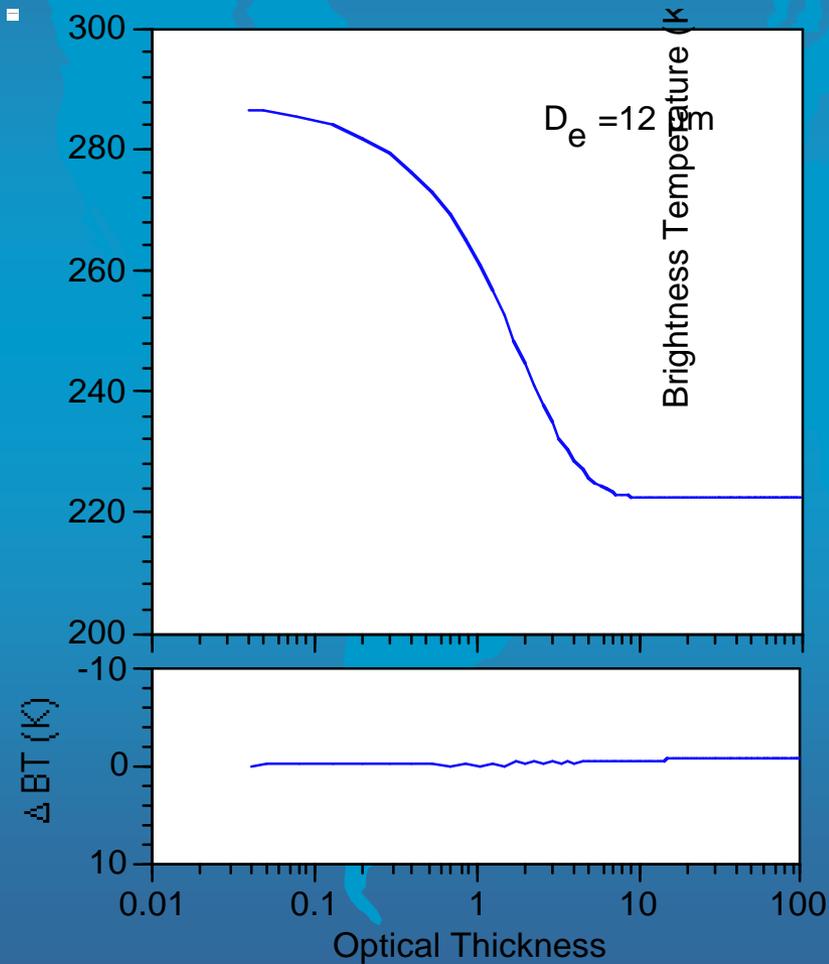

Comparison of the results from the fast model and the DISORT model

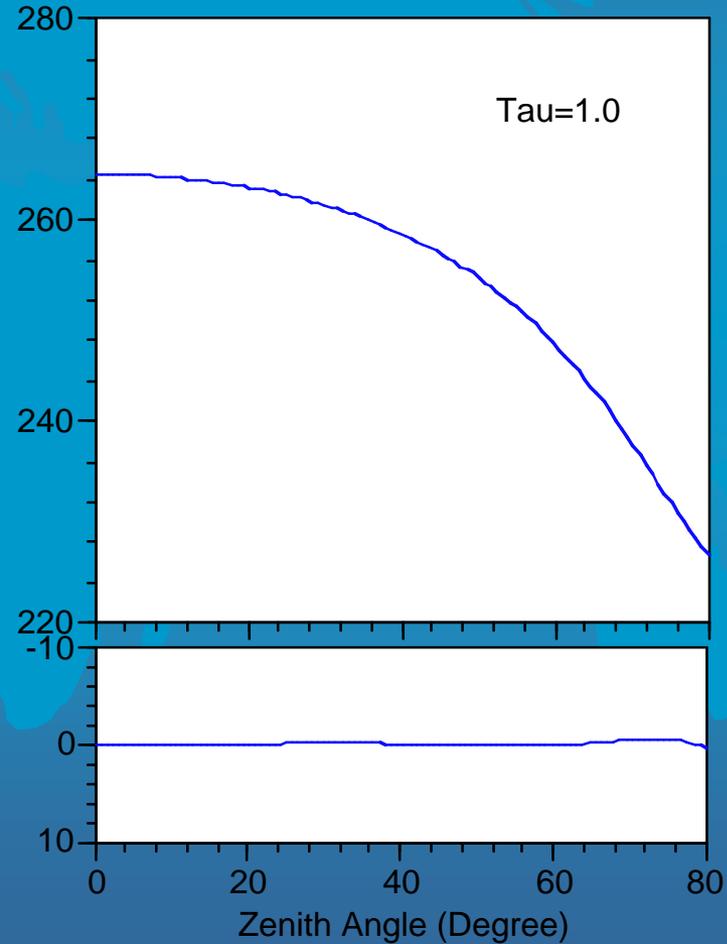

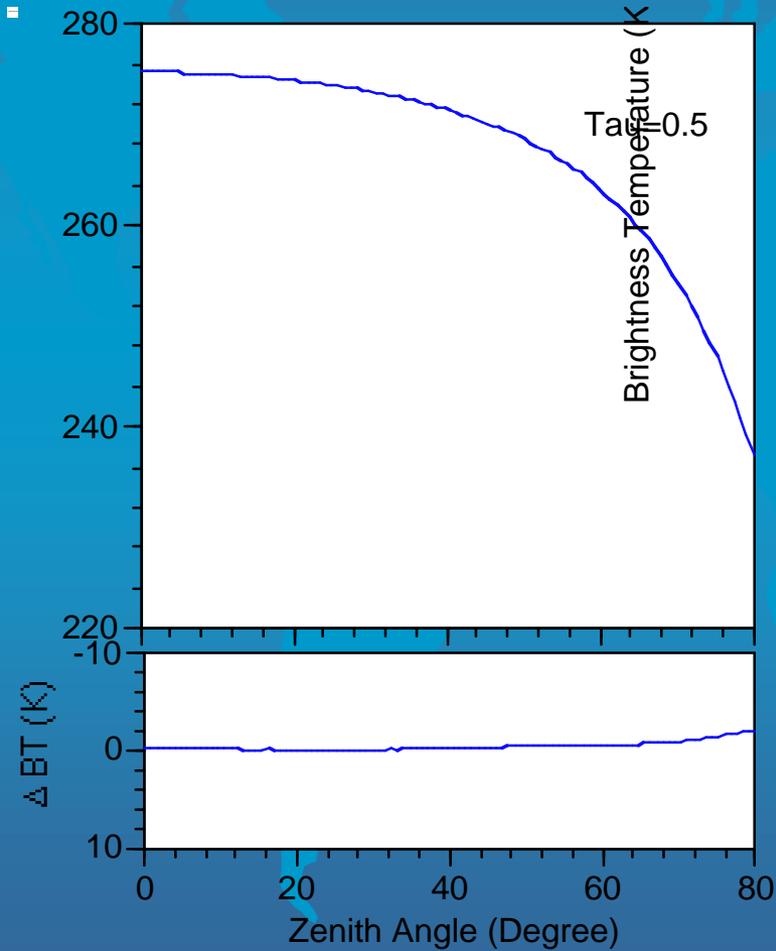

Comparison of the results from the fast model and DISORT (variation of BT versus effective size)

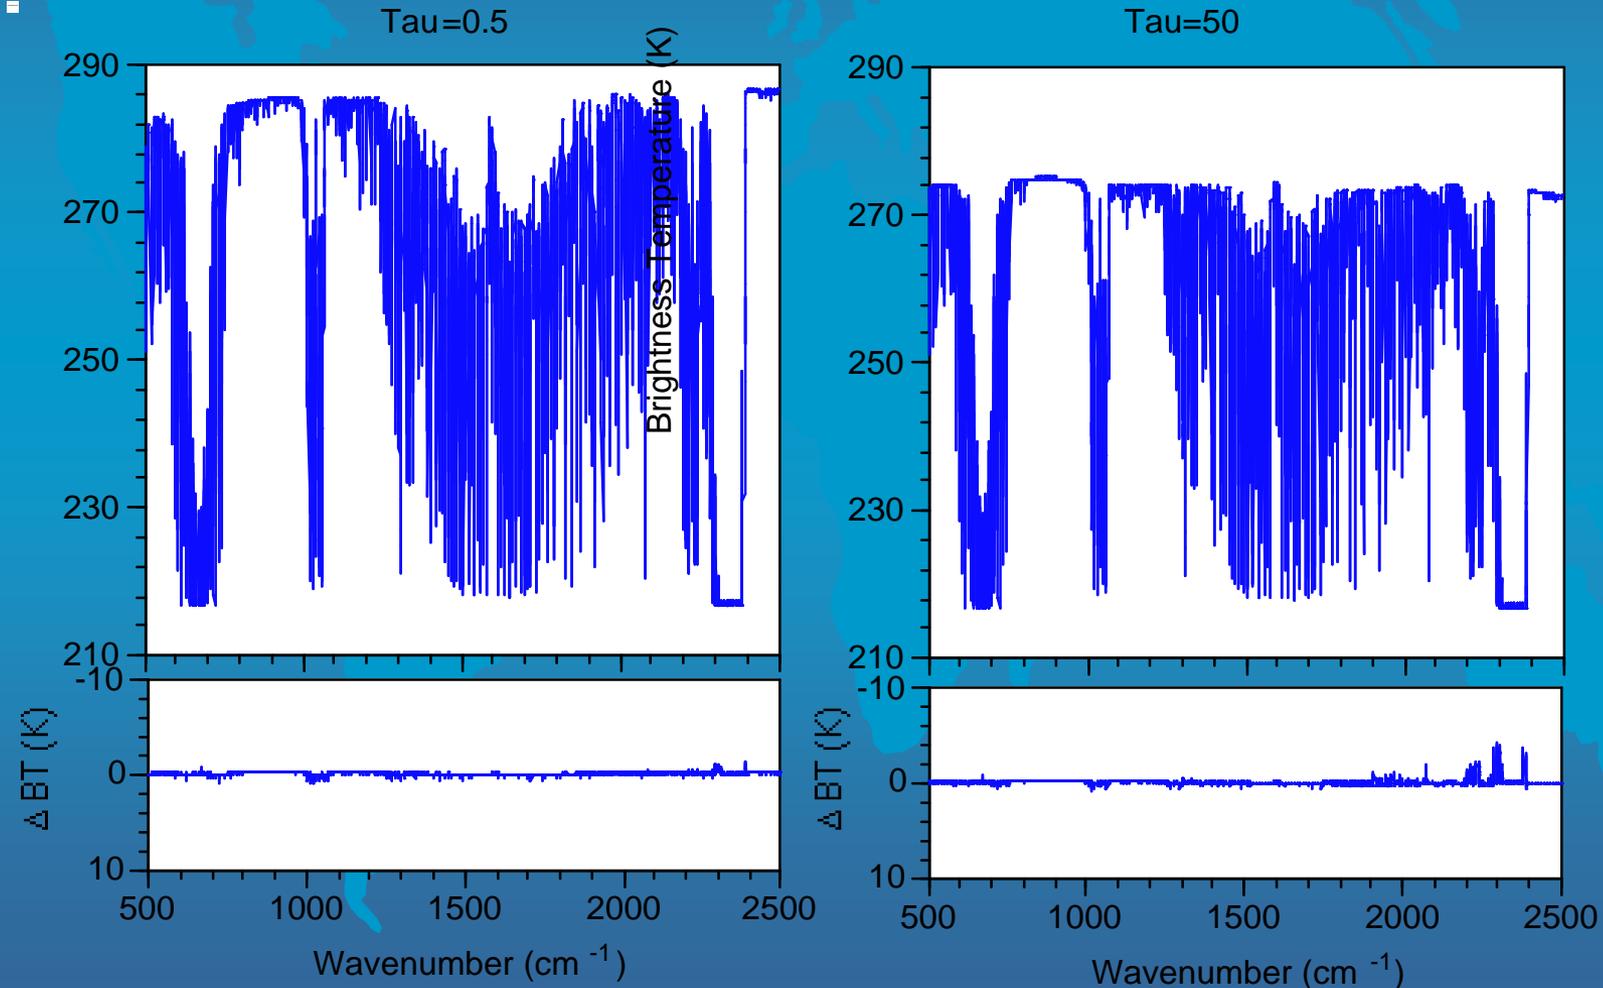

Comparison of the results from the fast model and DISORT (variation of BT versus optical thickness)

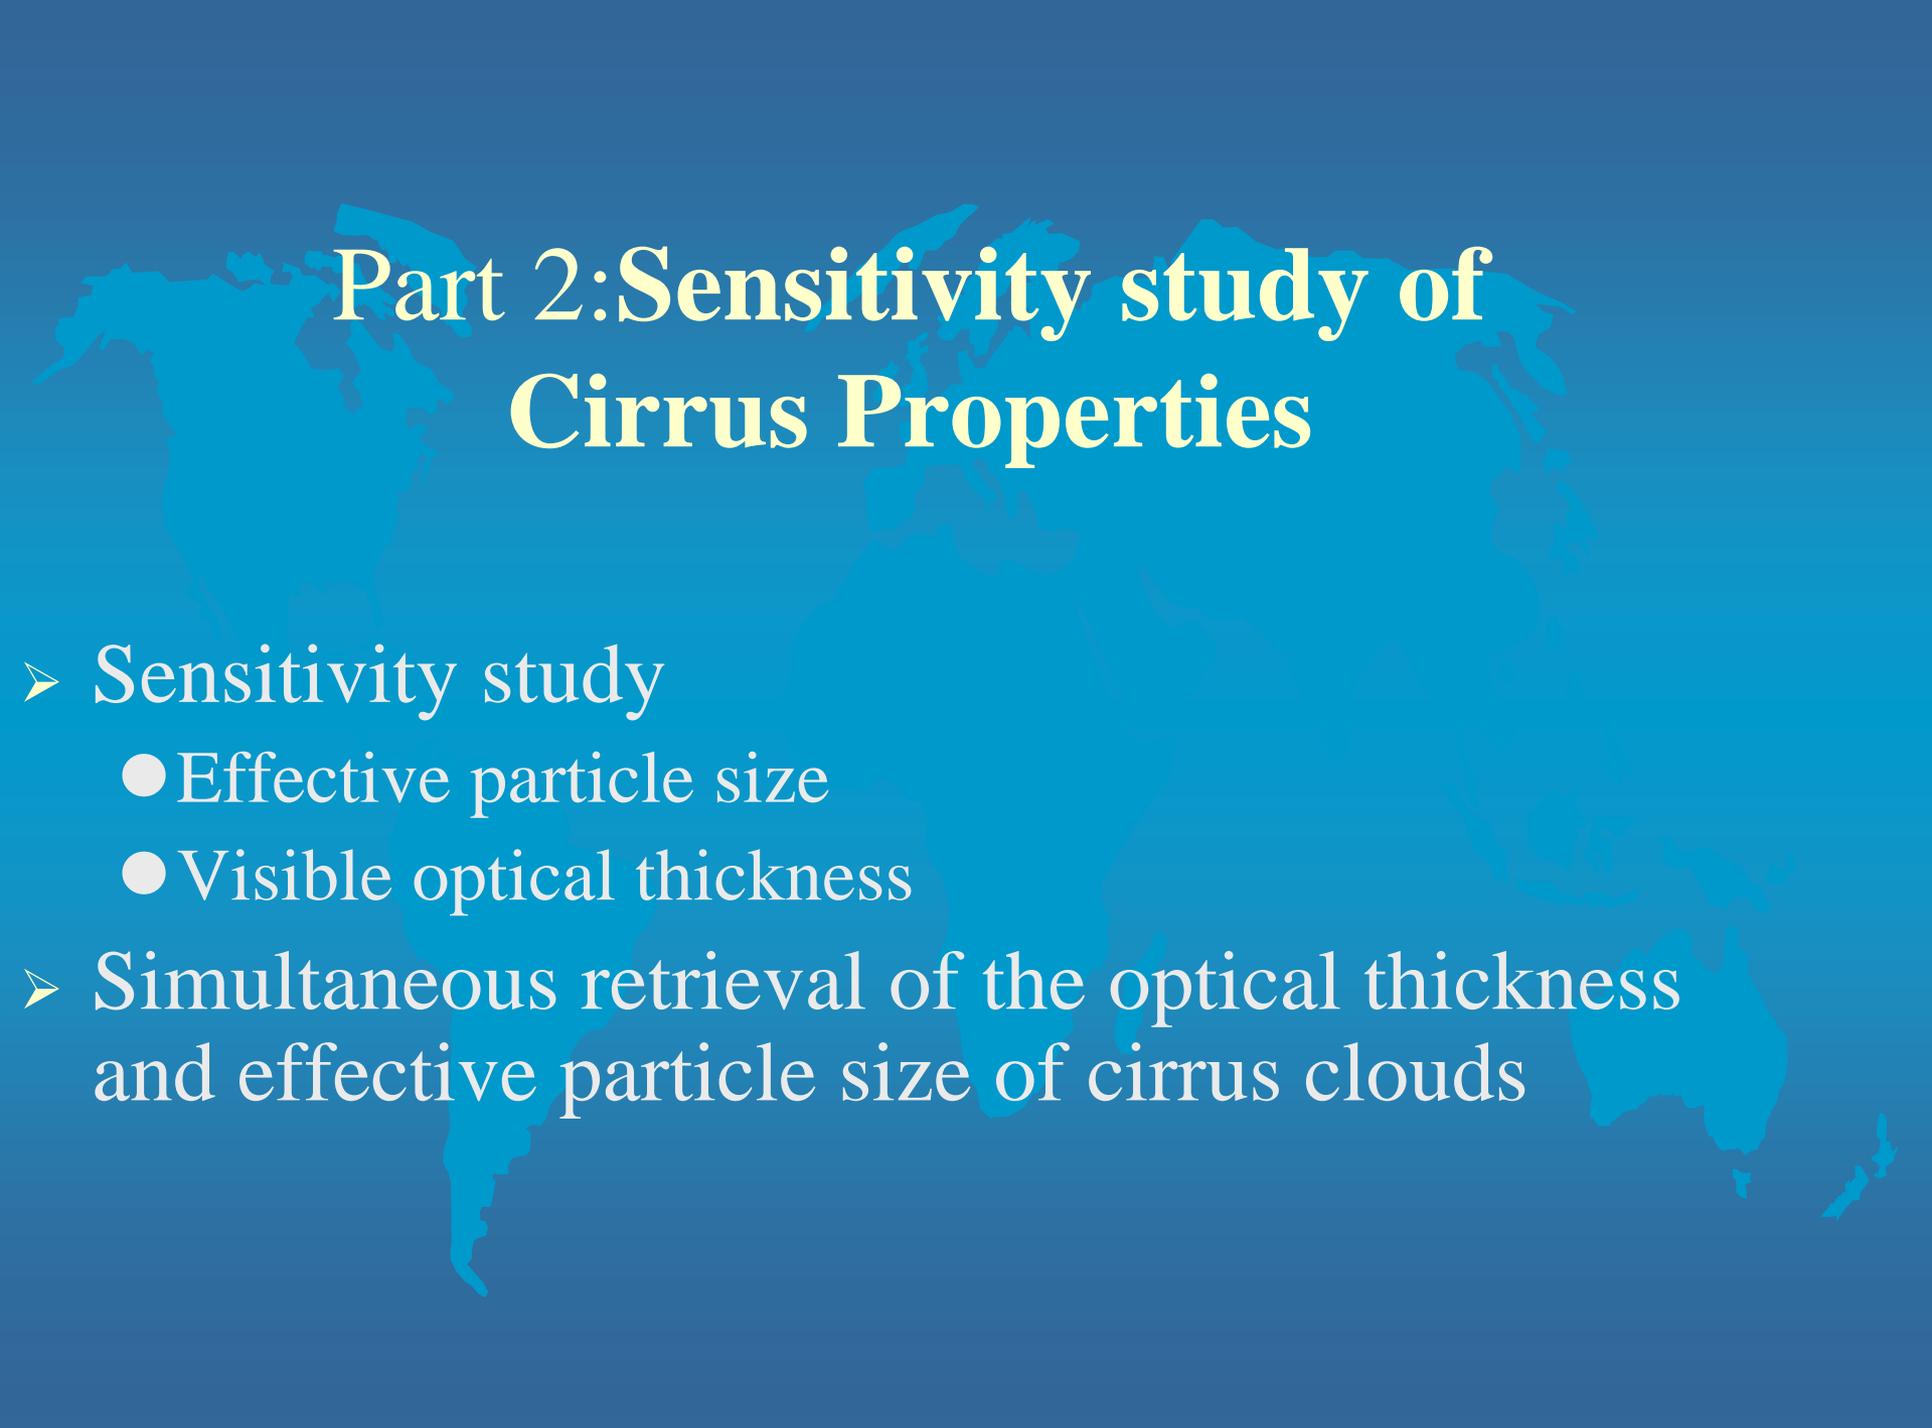

Comparisons the results of the fast model to DISORT (variation of BT versus zenith angle)

Comparisons the results of the fast model to DISORT for water clouds

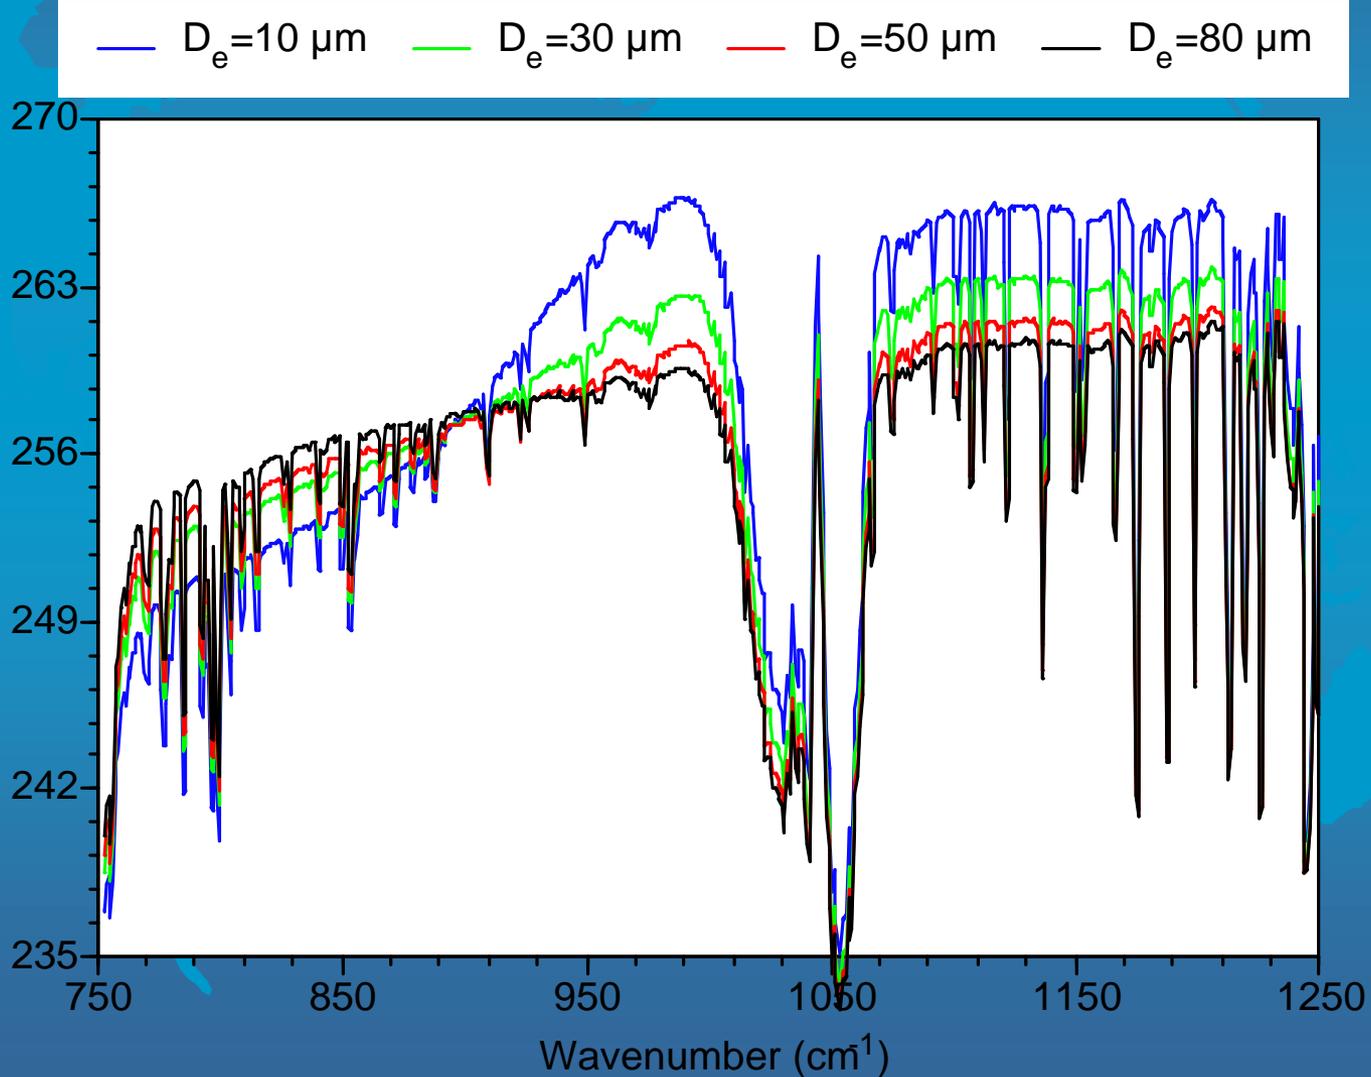

A faint, light blue world map is visible in the background of the slide, centered behind the text.

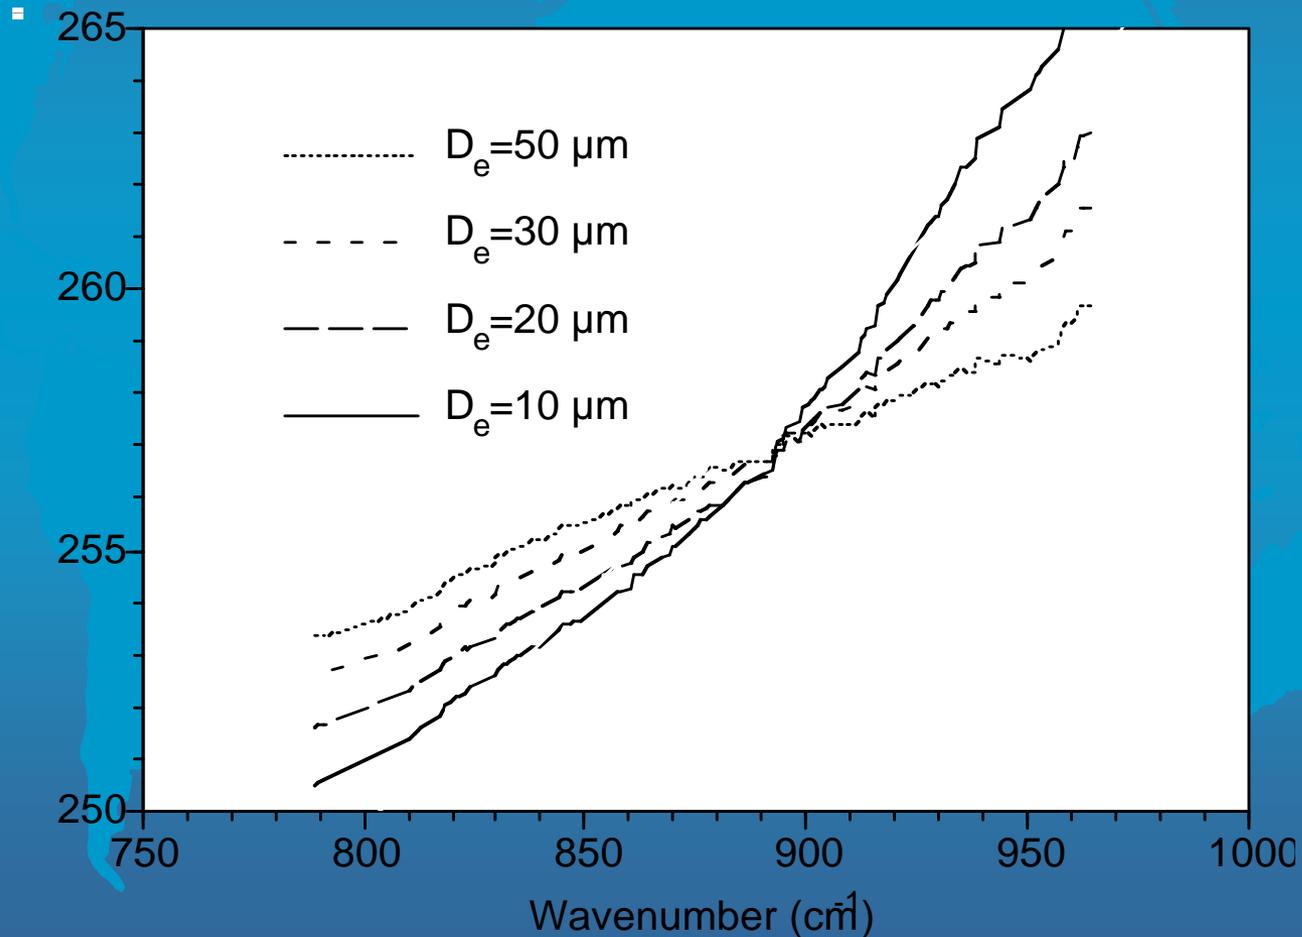

Part 2: Sensitivity study of Cirrus Properties

- Sensitivity study
 - Effective particle size
 - Visible optical thickness
- Simultaneous retrieval of the optical thickness and effective particle size of cirrus clouds

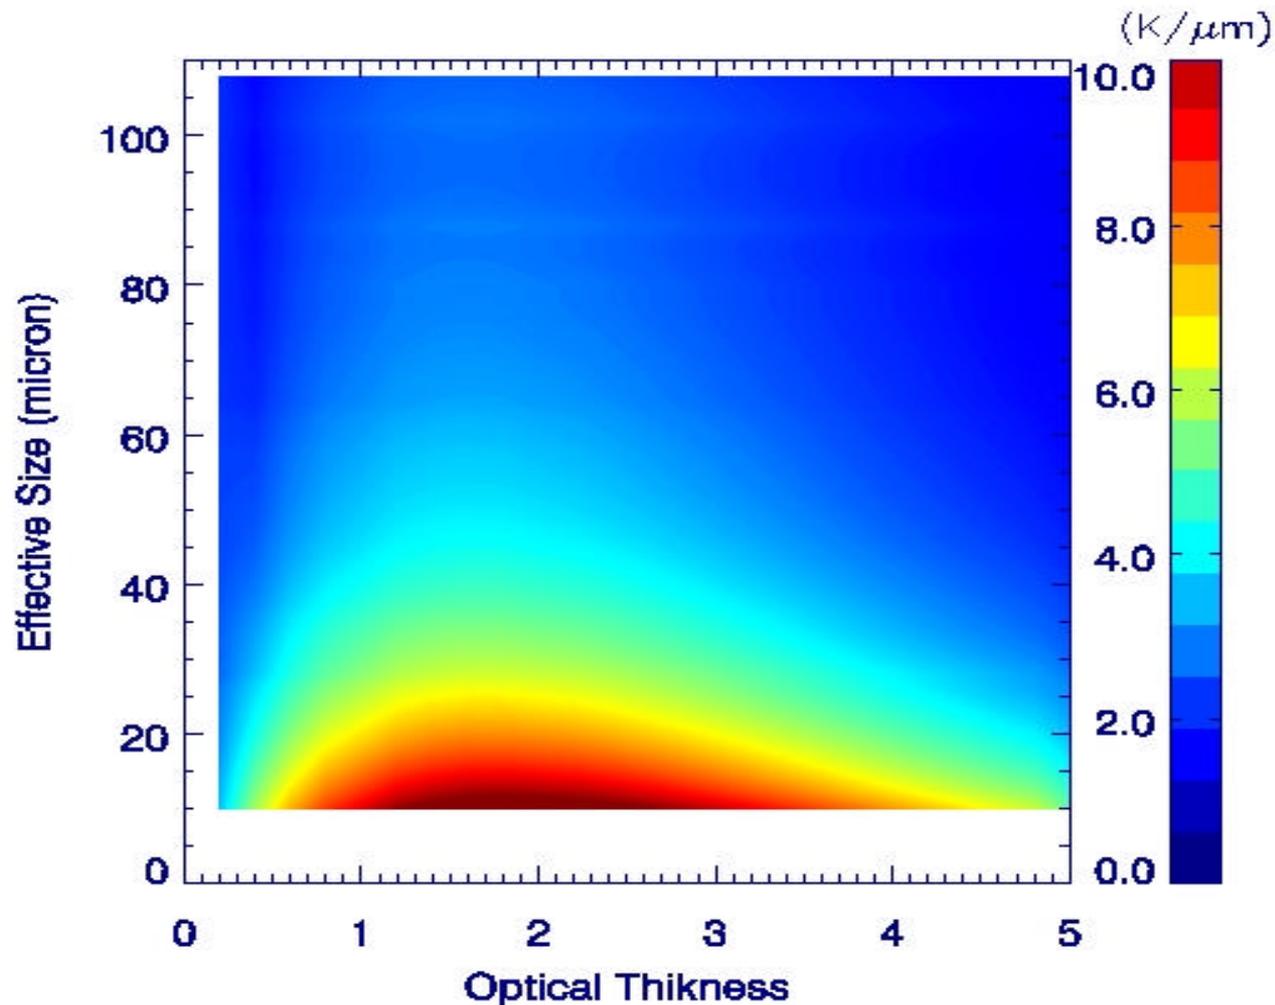

The sensitivity of upwelling brightness temperature to the effective size of cirrus clouds

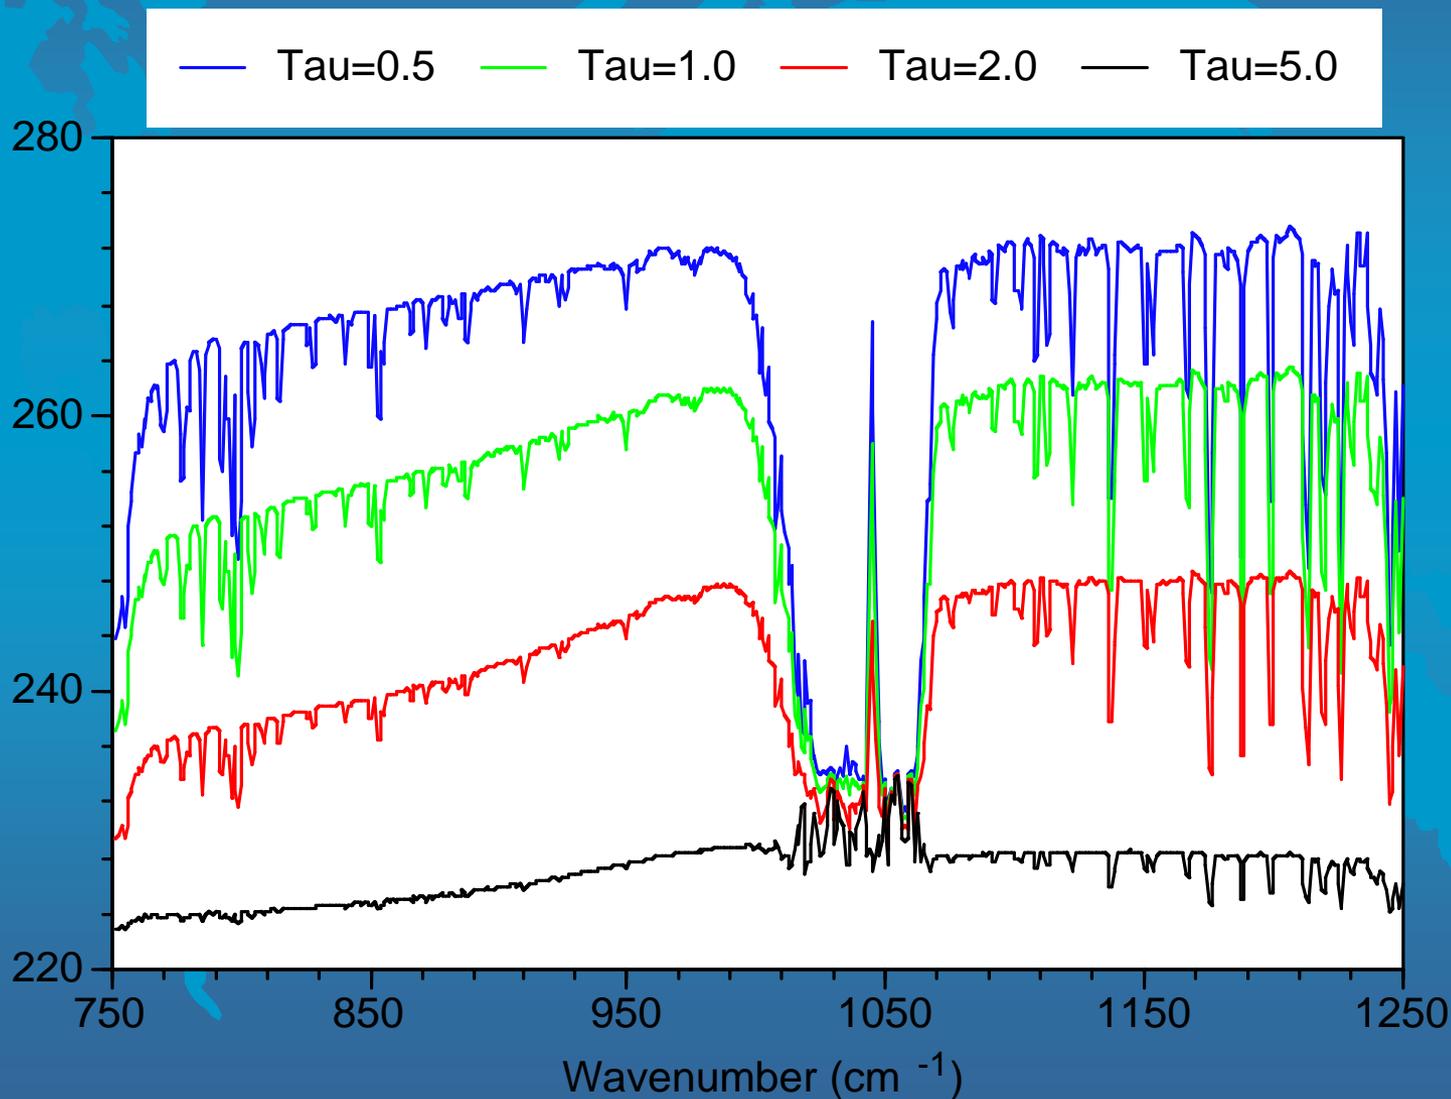

The sensitivity of the slope to the effective size of cirrus clouds

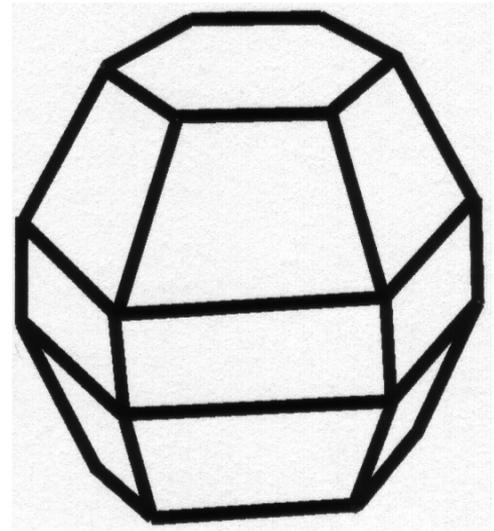

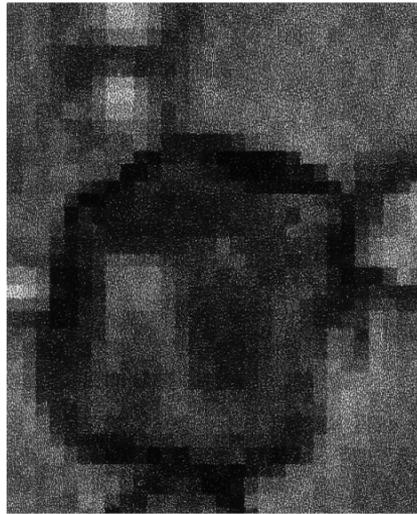

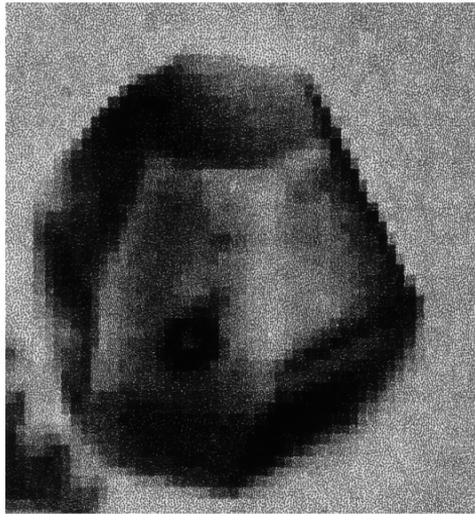

Sensitivity of the slope to the effective size and optical thickness of cirrus clouds

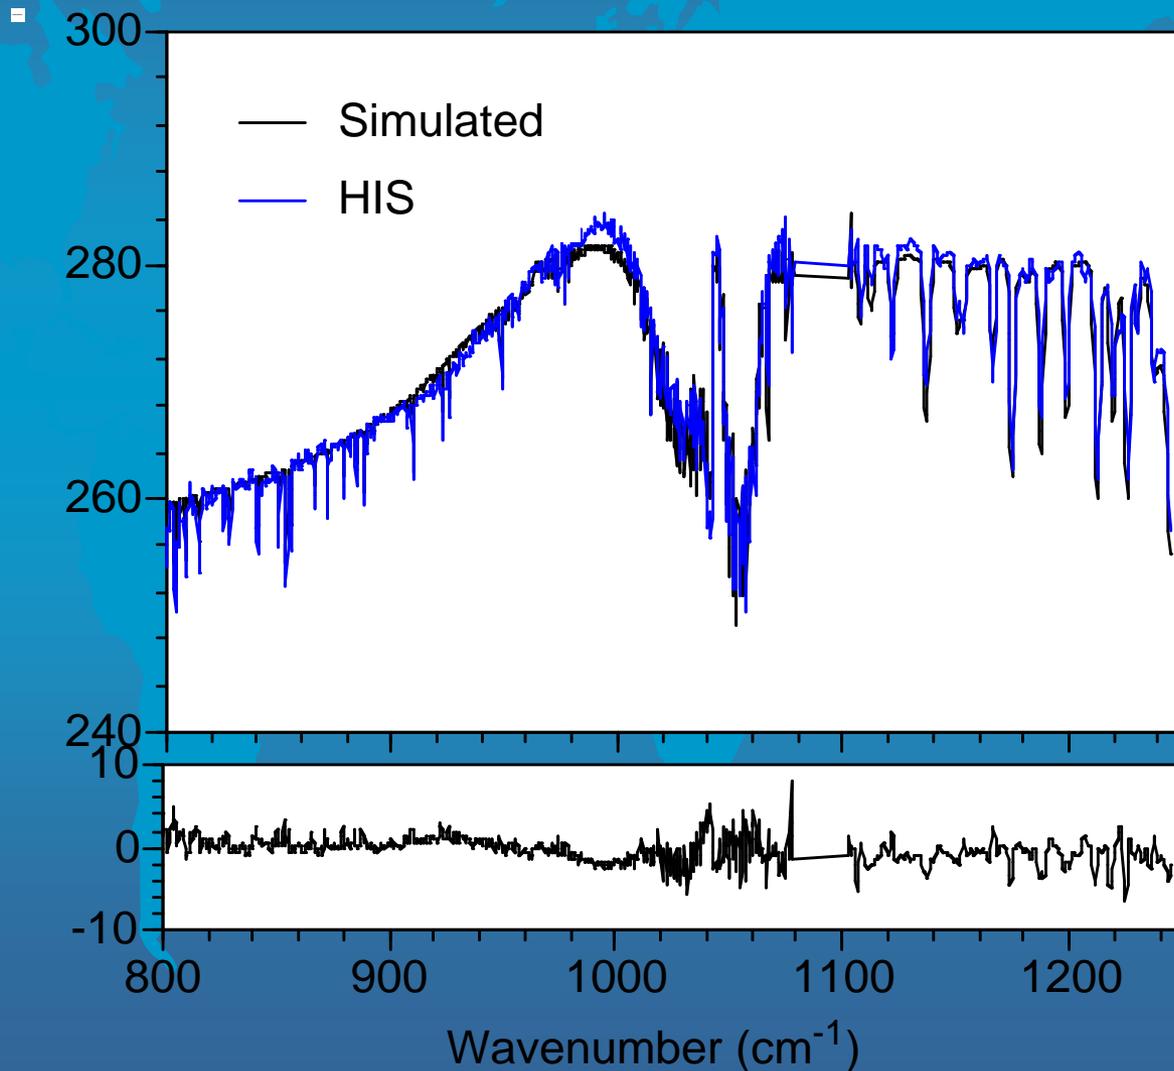

Sensitivity of upwelling brightness temperature to the optical thickness of cirrus clouds

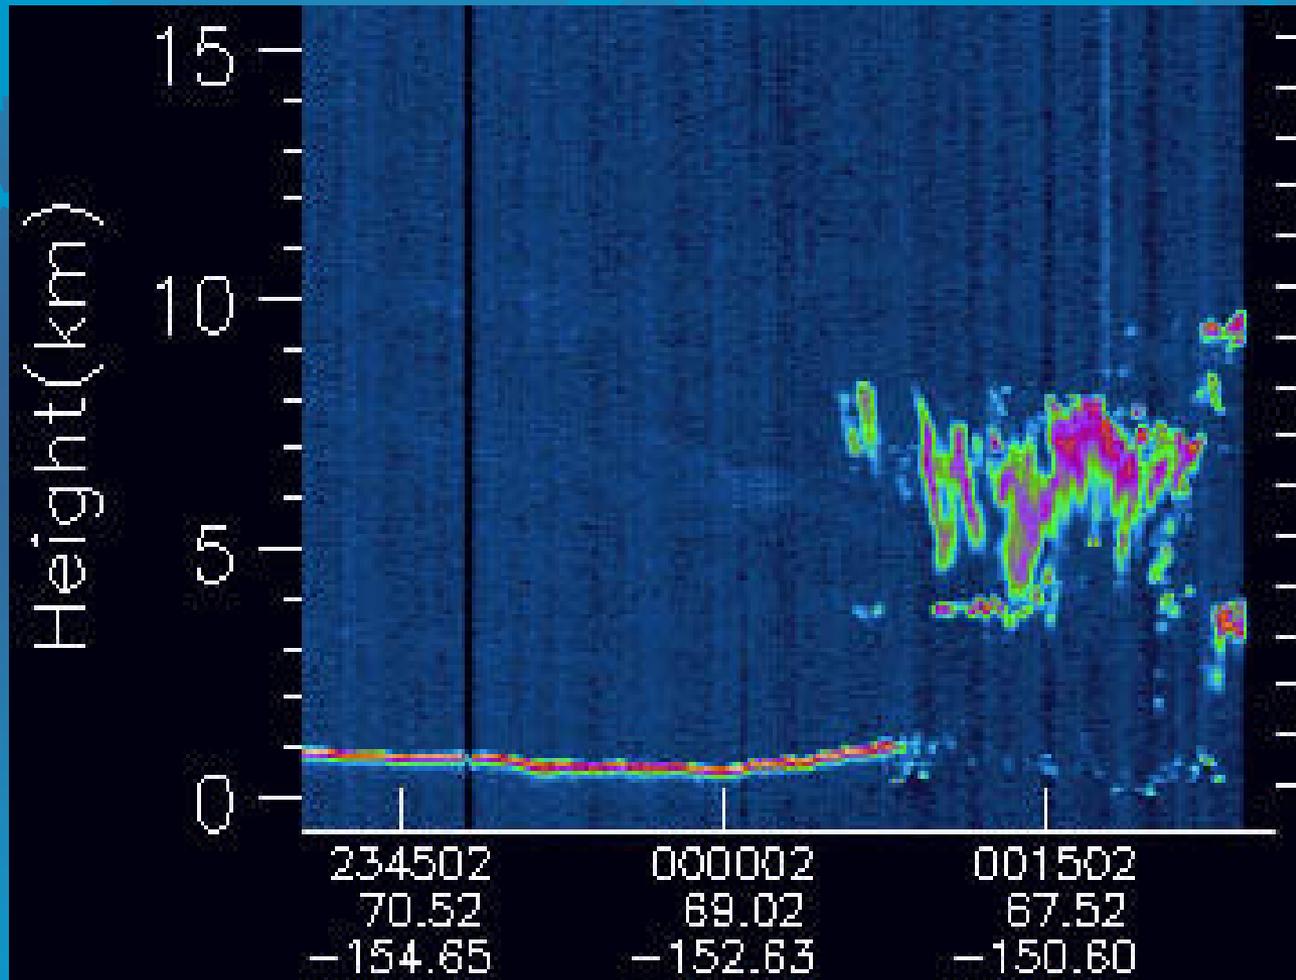

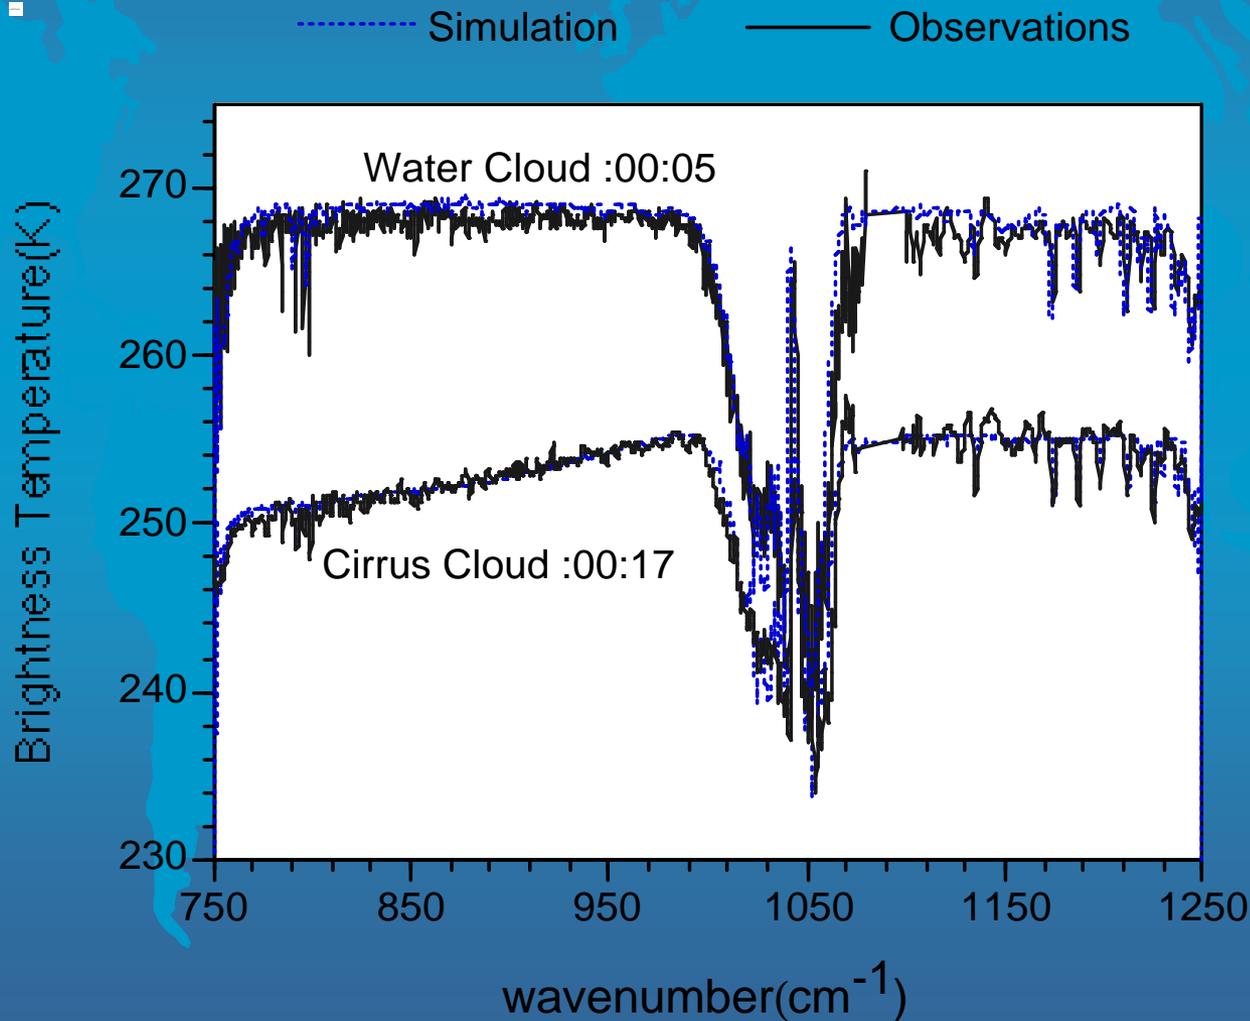

Comparison of observed and simulated upwelling IR spectra for a jet contrail composed of primarily small ice particles.

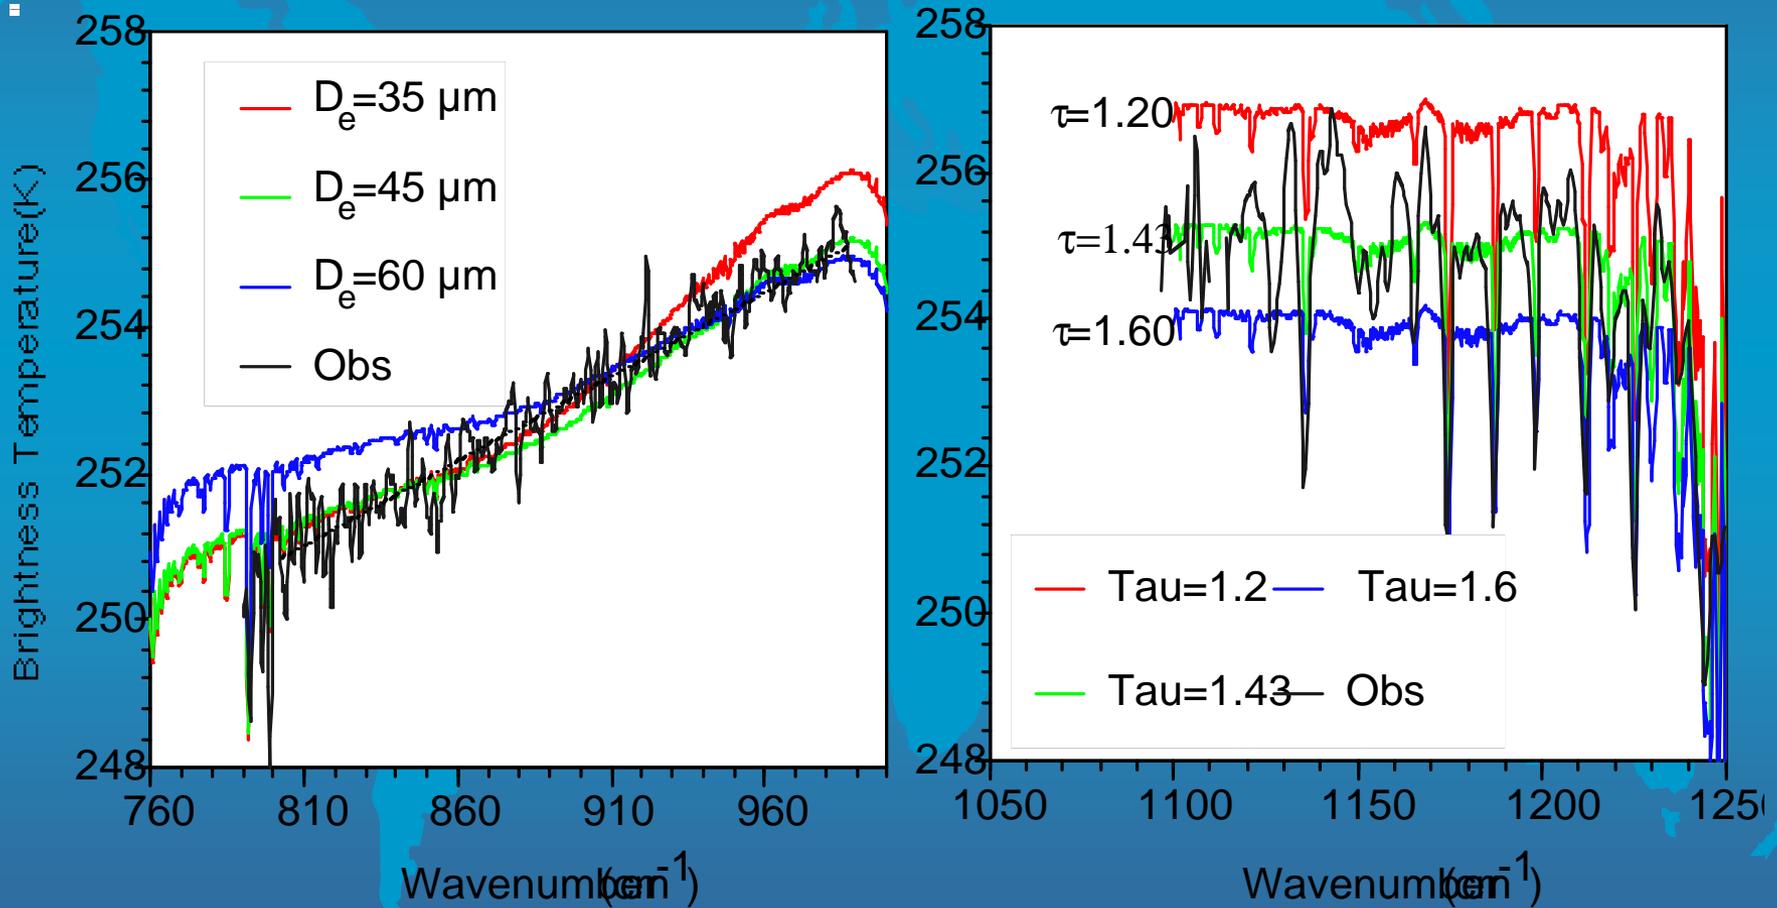

Cloud Lidar System (CLS) image

Observed and simulated upwelling IR spectra for cirrus and water cloud conditions

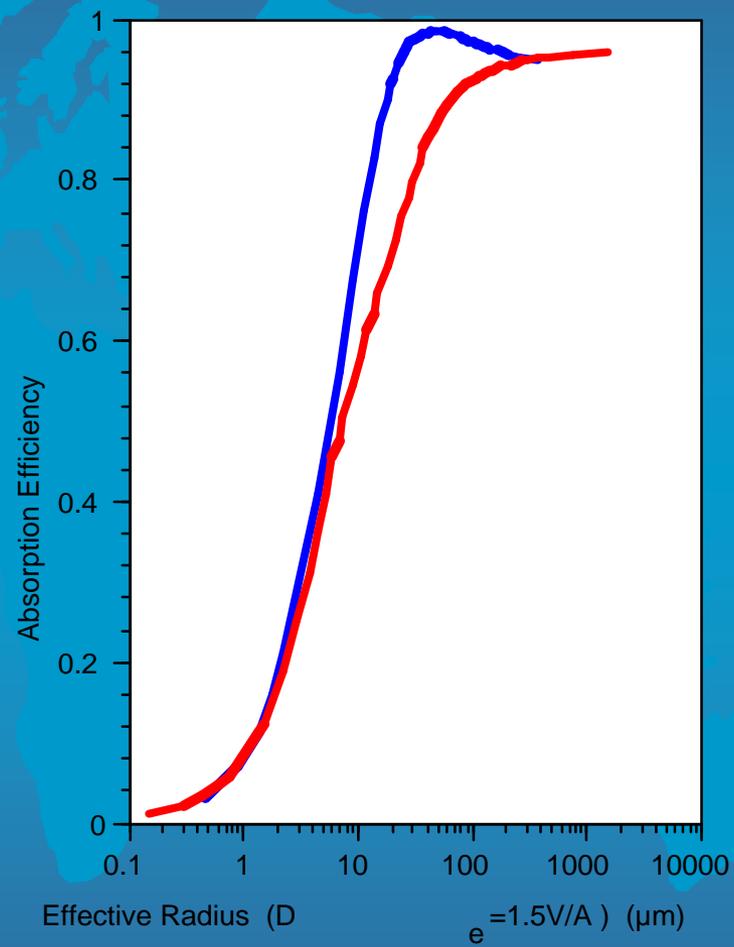

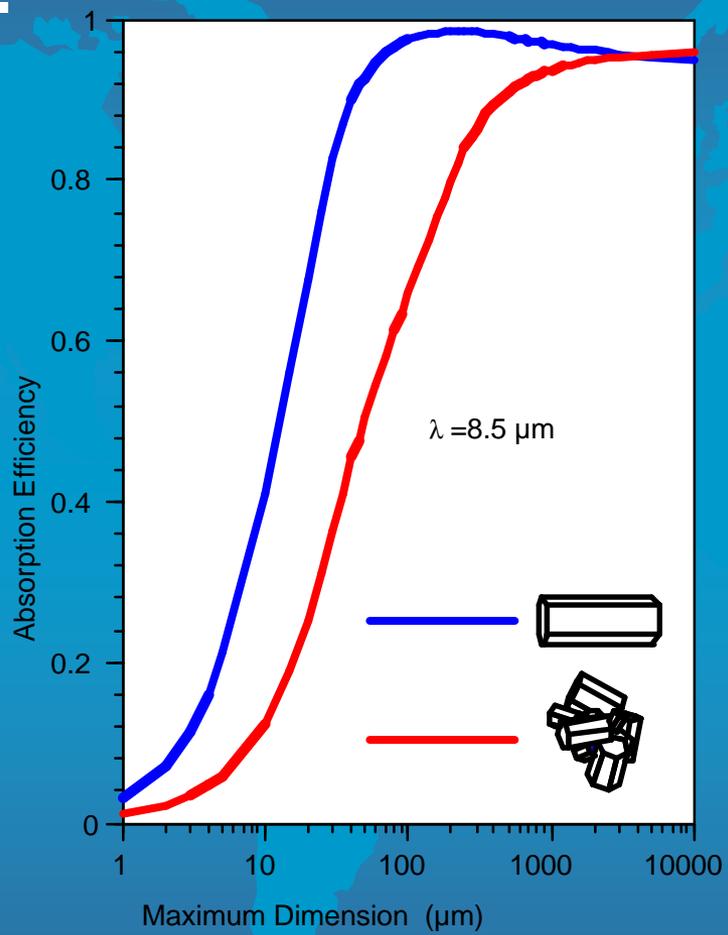

The simultaneous retrieval of the effective size and optical thickness from HIS spectra

Plan for Next Year

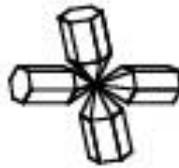

- Improve the modeling of the single-scattering properties of clouds (ice, water and mixed-phase clouds)
 - More realistic habits
 - Recent microphysical measurement (e.g., CRYSTAL-FACE data)
- Improve the speed and accuracy of the fast cloudy radiative transfer model
- Consider multi-layered cloud system
- Fast model for mixed-phase clouds
